Aspirin blocks formation of metastatic intravascular niches by inhibiting platelet-derived COX-1/thromboxane A2

Serena Lucotti, … , Anne J. Ridley, Ruth J. Muschel

Because metastasis is associated with the majority of cancer-related deaths, its prevention is a clinical aspiration. Prostanoids are a large family of bioactive lipids derived from the activity of cyclooxygenase-1 (COX-1) and COX-2. Aspirin impairs the biosynthesis of all prostanoids through the irreversible inhibition of both COX isoforms. Long-term administration of aspirin leads to reduced distant metastases in murine models and clinical trials, but the COX isoform, downstream prostanoid, and cell compartment responsible for this effect are yet to be determined. Here, we have shown that aspirin dramatically reduced lung metastasis through inhibition of COX-1 while the cancer cells remained intravascular and that inhibition of platelet COX-1 alone was sufficient to impair metastasis. Thromboxane A2 (TXA2) was the prostanoid product of COX-1 responsible for this antimetastatic effect. Inhibition of the COX-1/TXA2 pathway in platelets decreased aggregation of platelets on tumor cells, endothelial activation, tumor cell adhesion to the endothelium, and recruitment of metastasis-promoting monocytes/macrophages, and diminished the formation of a premetastatic niche. Thus, platelet-derived TXA2 orchestrates the generation of a favorable intravascular metastatic niche that promotes tumor cell seeding and identifies COX-1/TXA2 signaling as a target for the prevention of metastasis.

Because metastasis is associated with the majority of cancer-related deaths, its prevention is a clinical aspiration. Prostanoids are a large family of bioactive lipids derived from the activity of cyclooxygenase-1 (COX-1) and COX-2. Aspirin impairs the biosynthesis of all prostanoids through the irreversible inhibition of both COX isoforms. Long-term administration of aspirin leads to reduced distant metastases in murine models and clinical trials, but the COX isoform, downstream prostanoid, and cell compartment responsible for this effect are yet to be determined. Here, we have shown that aspirin dramatically reduced lung metastasis through inhibition of COX-1 while the cancer cells remained intravascular and that inhibition of platelet COX-1 alone was sufficient to impair metastasis. Thromboxane A₂ (TXA₂) was the prostanooid product of COX-1 responsible for this antimitastatic effect. Inhibition of the COX-1/TXA₂ pathway in platelets decreased aggregation of platelets on tumor cells, endothelial activation, tumor cell adhesion to the endothelium, and recruitment of metastasis-promoting monocytes/macrophages, and diminished the formation of a premetastatic niche. Thus, platelet-derived TXA₂ orchestrates the generation of a favorable intravascular metastatic niche that promotes tumor cell seeding and identifies COX-1/TXA₂ signaling as a target for the prevention of metastasis.

Introduction

Prostanoids are a family of bioactive lipids comprising prostaglandins (e.g., PGD₂, PGE₂, PGF₂α), thromboxane A₂ (TXA₂), and prostacyclin (PGI). The rate-limiting step of prostanoid biosynthesis is catalyzed by cyclooxygenase (COX), an enzyme with 2 isoforms, COX-1 and COX-2. Both COX-1 and COX-2 have virtually identical enzymatic activity, mediating the conversion of arachidonic acid into PGG₂ and then into PGH₂, the common precursor of all prostanoids (1). However, the spectrum of prostanoids synthesized by each isoform differs in vivo as a result of distinct expression patterns and functional coupling to prostanoid synthases in different cell types (2). For example, COX-2 is induced in endothelial cells and macrophages during inflammation and wound healing and couples with PGE₂ synthase in those cells to produce proinflammatory PGE₂ (2, 3). In contrast, COX-1 is constitutively expressed. In platelets COX-1 couples with TXA₂ synthase (TXAS) to generate prothrombotic TXA₂ upon procoagulant stimuli (e.g., collagen, thrombin, and adenosine diphosphate [ADP]) (4–6). Because of the differential expression of prostanoid synthases and COX-1 and COX-2, the activity of the 2 isoforms is rarely redundant.

The importance of COX and prostanoid pathways in metastasis is apparent from reports showing that their inhibition greatly curtails metastasis. NSAIDs, including aspirin, that inhibit both COX-1 and COX-2 generally reduce metastasis in clinical studies and murine models (7–9). In some reports specific COX-2 inhibition blocks metastasis (10, 11), but not in others (12). Looking at the downstream prostanoids, inhibition of TXA₂ or of PGE₂ synthesis also reduces metastasis in animal models, while PGI has been reported to inhibit metastasis (11–18), with some exceptions (12, 19). These reports raise the question of whether some prostanoids might be suitable targets for metastasis prevention or therapy.

The possibility of using COX or prostanoid synthesis inhibition as a preventive strategy for metastasis has been highlighted by both clinical and experimental studies. Aspirin is given clinically in a variety of doses to reduce cardiovascular events or inflammation. Because of its unique combination of irreversible inhibition of COX enzymes and short circulating half-life, low-dose aspirin preferentially inhibits COX-1 in platelets, reducing the production of prothrombotic TXA₂ and other prostanoids (20). Thus, low-dose aspirin is given for prophylaxis of myocardial infarction and stroke. Higher doses of aspirin inhibit both COX isoforms in other tissues (21). In particular, the reduction of COX-2-derived PGE₂ exerts antinflammatory effects. Case-control studies and meta-analysis of randomized controlled trials have shown that aspirin given for these unrelated purposes reduces metastatic cancer (22, 23). This effect was significant over a range of primary tumor types, with a
they are crucial and which prostanoids might be responsible for their effects.

Here we demonstrate using a variety of different models that specific inhibition of COX-1 in platelets is sufficient to inhibit metastasis to the same extent as aspirin whereas inhibition of COX-2 does not reduce metastatic colonization. We further show that COX-1 blockade leading to inhibition of TXA2 synthesis in platelets is sufficient to inhibit metastasis. Lastly we provide evidence that the antimetastatic effect of COX-1 inhibition is generally limited to the early stages of metastasis and that inhibition of COX-1 or of TXA2 synthesis prevents the formation of an intravascular metastatic and premetastatic niche.

**Results**

**Reduction of metastasis by aspirin correlates with the inhibition of thrombosis.** We treated mice with different doses of aspirin (ASA; low, medium, and high), which were based on the low, medium, and high doses used in humans according to a body surface area dose conversion method and on previous literature (8, 36–38). Inhibition of COX-1 was evaluated using serum levels of TXB2, a stable metabolite of TXA2 generated by platelet COX-1 activity during clotting (ex vivo) (Figure 1A and ref. 39). Greater than 95% reduction in TXB2, ex vivo is thought to indicate physiological inhibition of COX-1 (40). The medium and high doses, but not the low dose, of aspirin reduced TXB2 more than 95% (Figure 1B) and, accordingly, reduced COX-1-dependent (arachidonic acid and U46619, a stable analog of TXA2) agonist-induced platelet aggregation (Figure 1, C and D). COX-1-independent (ADP) platelet aggregation was not affected (Figure 1, C and D). Importantly, low-dose aspirin did not reduce serum TXB2 more than 95% over 6 days after the treatment began, suggesting that the drug does not accumulate over time (Supplemental Figure 1; supplemental material available online with this article; https://doi.org/10.1172/JCI121985DS1).
Spontaneous metastasis was also inhibited by aspirin. BALB/c mice with 4T1-GFP–derived subcutaneous tumors received vehicle or aspirin treatment (Figure 2E). Tumor growth was similar in both treatment groups, although aspirin treatment was associated with enhanced tumor regression (Supplemental Figure 4A). Aspirin decreased numbers of lung and liver metastases, of disseminated tumor cells in the lungs (Figure 2, F–I), and of circulating tumor cells (CTCs) (Supplemental Figure 4B) and the invasive ability of those CTCs (Supplemental Figure 4, C–E). These data confirmed the inhibitory effect of aspirin on metastasis at doses that inhibit COX-1 activity and thrombosis, suggesting that aspirin affects metastasis establishment through an antithrombotic effect.

COX-1 inhibition is sufficient to reduce metastasis. Since aspirin inhibits both COX-1 and COX-2 at metastasis-suppressive doses, we determined the effect on metastasis of selective inhibitors of COX-1 (SC-560) or COX-2 (NS-398). Isoform specificity was confirmed by reduction of serum TXB$_2$ for COX-1 (Figure 3A) and plasma PGE$_2$ for COX-2 (Figure 3B and Supplemental Figure 2). COX-1 inhibition by SC-560 significantly reduced the number of metastatic lung nodules from B16F10 cells (Figure 3, C and D) compared to the medium and high doses of aspirin (Figure 2B). COX-2 inhibition by NS-398 did not reduce the numbers (Figure 3, C and D), making it unlikely that metastatic seeding requires PGE$_2$. However, NS-398–treated mice had smaller metastatic colonies (Figure 3, E and F), compatible with the reported involvement of COX-2 in tumor cell proliferation (15). Using other models, SC-560 also reduced experimental lung metastasis from MC-38-GFP, 4T1, and MDA-MB-231-CFP cells (Supplemental Figure 3) and spontaneous lung and liver metastasis, pulmonary dissemination (Figure 3, G–J), and CTCs and their invasiveness from 4T1-GFP tumor-bearing mice (Supplemental Figure 4, B–E).

Fewer experimental metastases were generated by B16F10 cells in COX-1–/– (PtgS1–/–, indicated here as COX-1–/–) mice than in wild-type (COX-1+/+) (Figure 4, A and B). As expected, COX-1–/–
mice had decreased serum TXB₂ levels (Figure 4C) and reduced platelet aggregation (Figure 4, D and E) compared with COX-1+/+ mice. Taken together, these data indicate that the inhibition of COX-1 is sufficient to impair metastasis development. They further suggest that inhibition of COX-1 mimics the antmitotic effect of aspirin. These results led us to ask (a) what phase of metastasis is affected by inhibition of COX-1; (b) which product of COX-1 enables metastasis; and (c) which COX-1-expressing cells are responsible for these effects.

**Activity of COX-1 is required during the intravascular phase of metastasis.** Disseminating tumor cells remain in the bloodstream for 1–4 days prior to extravasation, a time that varies depending on the model used (43). After tail vein injection, B16F10 cells were mainly intravascular after 24 hours and underwent extravasation between days 1 and 3 with the majority extravasated by day 4 (Supplemental Figure 5, A and B). The number of B16F10 cells rapidly decreased after injection, with only approximately 25% of the total adhered cells surviving in the lung vasculature 1 day after injection (Supplemental Figure 5C). Multicellular colonies were first noted on day 3, and micrometastases were seen on day 4 (Supplemental Figure 5, C and D). With day 0 being the day of injection, treatment was given from day –2 to day +1 (–2 → +1) for the intravascular phase, from day +1 to day +4 (+1→+4) for the extravasation phase, or from day +4 to day +21 (+4→+21) for the extravascular phase (Figure 5A). Aspirin and SC-560 given during the intravascular phase of metastasis resulted in reduced numbers of metastatic lung nodules similar to treatment throughout. In contrast, administration during the later extravasation and extravascular phases did not affect metastasis (Figure 5, B and C). NS-398 did not change metastasis regardless of the schedule (Figure 5D). Aspirin and SC-560, but not NS-398, reduced the number of tumor cells in the lung 24 hours after injection (Figure 5, E and F). A similar reduction was obtained in COX-1−/− mice (Figure 5, E and F). These findings suggest that COX-1 in host cells, rather than in tumor cells, is required for the pulmonary retention of tumor cells and the onset of metastasis.

**TXA₂ signaling driven by COX-1 is essential for metastasis.** Circulating TXA₂ is the most abundant product of COX-1 in the circulatory system, mainly produced by activated platelets (4). To ask whether TXA₂ was a critical intermediary in the COX-1-dependent development of metastasis, we administered picotamide (PICO), a dual inhibitor of TXAS and antagonist of TXA₂ receptor (TP), to mice (Figure 6A) (44). This treatment reduced...
TXA2 is synthesized by activated platelets and is a potent agonist levels of plasma TXA2/TXB2 (Figure 7A) and platelet aggregation (Figure 6B) and platelet aggregation (Figure 7, B and C) in aspirin-treated mice. This restored basal TXA2 synthesis by COX-1 in platelets is required for metastasis (26, 45). Fluorescently labeled B16F10 cells (B16F10-CMAC) and platelets (Plts-PKH26) were injected into the opposite tail veins of mice. Platelet aggregation was observed only in the vicinity of the tumor cells, not distantly (Supplemental Figure 7A), suggesting that aggregation was triggered by the tumor cells. Additionally, platelets neither aggregated nor associated with the lung vasculature of naive mice (Supplemental Figure 7B), excluding the possibility that platelet aggregation resulted from euthanasia and its accompanying decreased blood flow. Treatment with aspirin, SC-560, and picotamide, but not NS-398, decreased the number and the size of clots per tumor cell (Figure 8, A–C). Similar results were obtained after coinoculation of the 2 cell populations in vitro (Supplemental Figure 8, A–C). Pretreatment of platelets with aspirin and SC-560 diminished platelet aggregation on tumor cells, while pretreatment of tumor cells had no effect (Supplemental Figure 8, D–F). Additionally, COX-1+/+ platelets, but not COX-1−/− platelets, B16F10 cells, nor primary lung microvascular endothelial cells (LMVECs) cells, generated TXB2 either alone or in coculture of naive mice (Supplemental Figure 7B), excluding the possibility that platelet aggregation resulted from euthanasia and its accompanying decreased blood flow. Treatment with aspirin, SC-560, and picotamide, but not NS-398, decreased the number and the size of clots per tumor cell (Figure 8, A–C). Similar results were obtained after coinoculation of the 2 cell populations in vitro (Supplemental Figure 8, A–C). Pretreatment of platelets with aspirin and SC-560 diminished platelet aggregation on tumor cells, while pretreatment of tumor cells had no effect (Supplemental Figure 8, D–F). Additionally, COX-1+/+ platelets, but not COX-1−/− platelets, B16F10 cells, nor primary lung microvascular endothelial cells (LMVECs) cells, generated TXB2 either alone or in coculture (Figure 8D). Thus, COX-1 in platelets associated with B16F10 cells is a major source of TXA2, and its inhibition affects platelet aggregation and thrombus expansion on tumor cells.

We then asked whether COX-1 inhibition in reintroduced platelets would reduce metastasis. After platelet depletion by R300 antibody, platelets isolated from vehicle-, ASA-, SC-560−, NS-398−, or PICO-treated mice (Figure 8, G and H) or COX-1+/+ platelets in both COX-1+/+ (Figure 8, E and F) and COX-1−/− (Supplemental Figure 9D) mice resulted in significantly greater pulmonary retention of tumor cells at 24 hours and enhanced numbers of metastatic lung colonies (Figure 8, G and H) compared with using COX-1+/+ platelets. Similarly, infusion of platelets from ASA−, SC-560−, and PICO-treated mice (Figure 8, G and H) or
platelet-poor plasma (Supplemental Figure 9C) did not restore lung metastasis formation. Platelets from NS-398–treated mice restored metastatic colony formation (Figure 8, G and H). Together these results establish platelets as the COX-1/TXA2–dependent compartment in the establishment of metastasis.

Inhibition of COX-1 reduces the adhesion of tumor cells to endothelium. Tumor cell adhesion to endothelial cells during hematogenous metastasis involves multiple mechanisms (46) and seems to be facilitated by interactions with platelets (47). We investigated tumor cell adhesion to monolayers of LMVECs in the presence of platelets under flow with a low shear stress of 0.05 dyn/cm². Firm tumor cell adhesion to LMVECs was measured after the flow was increased to a higher shear stress (1 dyn/cm²) (Supplemental Figure 10, A and B). Platelet aggregates adhered to tumor cells and formed bridges between tumor cells and LMVECs (Supplemental Figure 10C). Aspirin and SC-560 reduced the adhesion of tumor cells to LMVECs and the association of platelets with tumor cells (Supplemental Figure 10, D–F, and Supplemental Video 1). While the higher shear stress did not alter adhesion of the tumor cells, interestingly, it produced a significant dissociation of platelets from tumor cells under aspirin and SC-560 treatment (Supplemental Figure 10, G–I). These data suggest that COX-1 inhibition can reduce the adhesion of tumor cells to the endothelium.

The COX-1/TXA2 axis in platelets contributes to an intravascular metastatic niche. Microemboli are formed with tumor cells, platelets, and myeloid cells at sites of activated endothelium. The myeloid cells promote the survival of disseminating cells and their development into metastasis (27, 29, 32, 48). Using Cx3cr1gfp/+ mice to visualize monocytes and macrophages (27, 49), we found that aspirin (medium and high doses) and SC-560, but not NS-398 and picotamide, reduced clustering of monocytes/macrophages around the intravascular tumor cells (Figure 9, A and B). The magnitude of monocyte recruitment correlated with the extent of the platelet clots (Figure 9C). Treatment with aspirin, SC-560, and picotamide also reduced the extent of endothelial activation as indicated by E-selectin and VCAM-1 expression in vessels adjacent to platelet–tumor cell aggregates (Figure 9, D–F). Neither monocyte/macrophage recruitment nor endothelial activation was observed in naive mice (Supplemental Figure 7). Additionally, inhibition of COX-1/TXA2 was associated with a larger diameter of lung vessels (Supplemental Figure 11, A–C), suggesting a decrease of vasoconstriction that might further prevent the accumulation of aggregates.

Analogous effects resulted from coinfusion of COX-1–/– platelets and B16F10 cells in COX-1+/+ mice, with a decrease in platelet aggregation on tumor cells (Figure 10, A–C), association of tumor
cells with activated endothelium (Figure 10, D–F), diameter of blood vessels (Supplemental Figure 11, D–F), and recruitment of monocytes/macrophages to tumor cells (Figure 10, G and H) in comparison with mice infused with COX-1+/+ platelets.

The COX-1/TXA2 pathway contributes to a pulmonary premetastatic niche. The ability of disseminated tumor cells to colonize distant sites is enhanced by the systemic effects of a primary tumor, generating a premetastatic niche (50). To test the effect of inhibition of the COX-1/TXA2 axis in platelets, mice bearing B16F10 subcutaneous tumors were treated with aspirin and injected i.v. with tumor cells to induce lung metastasis before the occurrence of spontaneous metastasis (Figure 11A). Aspirin treatment was started after the initiation of tumor growth and interrupted 2 days before tumor cell injection to avoid a direct effect of platelet inhibition on metastatic seeding. The increased numbers of metastatic lung nodules, indicative of the establishment of a premetastatic niche, were completely abrogated by treatment with aspirin (Figure 11B). Aspirin did not affect the number of nodules in mice without subcutaneous tumors (Figure 11B), further supporting the prometastatic role of intact COX-1/TXA2 axis in platelets at the moment of tumor cell injection.

Lung preconditioning has been linked to the recruitment of myeloid cells with the support of the coagulation system (27, 51, 52). The numbers of Cx3CR1-GFP+ monocytes/macrophages in the lungs of mice bearing tumors were greater than those in lungs of naive mice. Aspirin abolished this increase in monocytes/macrophages in the lungs of mice bearing tumors (n = 8), as in Figure 12E. Control groups are the same as in Figure 2, F and H. Data are represented as mean ± SD (B, E, G, H, J, and K), median ± range (C). Unpaired t test, 2-tailed (B, E, and H); 1-way ANOVA with Tukey’s multiple-comparisons test (C, G, J, and K). *0.01 < P ≤ 0.05; **0.001 < P ≤ 0.01; ***P ≤ 0.001.

**Figure 6.** Inhibition of TXA2 signaling alters the intravascular phase of metastasis. (A) Diagram of the targets of picotamide (PICO) in platelets. (E and F) B16F10 metastatic lung nodules in C57BL/6 mice treated with vehicle or picotamide (n = 6) as in Figure 2A. (G) B16F10 metastatic lung nodules in C57BL/6 mice treated with vehicle or picotamide, as in Figure 3A (n = 10, 14, 10, 5, and 5). (H and I) Number of B16F10-CMFDA cells (white) (H) and representative tile scans (I) of the left lung of C57BL/6 mice treated with vehicle or picotamide (n = 12 and 6) 24 hours after the injection of tumor cells. Scale bars: 1 mm (black bar), 100 μm (white bar). (J and K) Single disseminated cells in lungs (J) and metastatic nodules in lungs (J) or liver (K) of BALB/c mice bearing a 4T1-GFP tumor, treated with vehicle or picotamide (n = 8), as in Figure 2E. Control groups are the same as in Figure 2, F and H. Data are represented as mean ± SD (B, E, G, H, J, and K), median ± range (C). Unpaired t test, 2-tailed (B, E, and H); 1-way ANOVA with Tukey’s multiple-comparisons test (C, G, J, and K). *0.01 < P ≤ 0.05; **0.001 < P ≤ 0.01; ***P ≤ 0.001.
We specifically required, we tested clopidogrel, an antagonist of the P2Y12 ADP purinergic receptor, and eptifibatide, an inhibitor of \(\alpha_{IIb}\beta_3\) integrin (also known as GPIIb/IIIa), both used clinically to reduce platelet aggregation (53–56). Clopidogrel and eptifibatide significantly reduced ADP-induced platelet aggregation (Figure 12, A and B) without affecting plasmatic TXB\(_2\) levels in vivo.

Figure 7. TXA\(_2\) analog U46619 abrogates the inhibition of metastasis by aspirin. (A) Plasma TXB\(_2\) in mice treated with vehicle, aspirin (medium dose), or aspirin supplemented with U46619 (ASA + U46619; \(n = 4\)). (B and C) Agonist-induced aggregation of platelets from mice treated with vehicle, aspirin, or aspirin + U46619 (\(n = 5\), 4, and 5). (D and E) Number of tumor cells (D) and representative tile scans (E) from left lungs of mice treated with vehicle, aspirin, or aspirin + U46619 (\(n = 6\), 6, and 5) 1 day after injection (B16F10-CMFDA, white). Scale bars: 1 mm (black bar), 100 \(\mu\)m (white bar). (F) Experimental design of aspirin with or without U46619 treatment. Two days before B16F10 cell injection, mice were treated with vehicle, aspirin, or aspirin + U46619 for 3 weeks (ASA + U46619) or supplemented until 1 day after injection, followed by treatment with aspirin alone [ASA + (U46619 \(-2\rightarrow+1\))]. (G and H) B16F10 metastatic lung nodules in mice treated with vehicle, aspirin, aspirin + U46619, or aspirin + (U46619 \(-2\rightarrow+1\)) (\(n = 9\), 10, 9, and 8). Data are represented as mean + SD (A, D, and G), median ± range (B). One-way ANOVA with Tukey’s multiple-comparisons test. *0.01 < \(P\) ≤ 0.05; **0.001 < \(P\) ≤ 0.01; ***\(P\) ≤ 0.001.

Data suggest that the establishment of a lung premetastatic niche depends on the COX-1/TXA\(_2\) pathway in platelets.

TXA\(_2\) signaling, not other platelet activation pathways, is required for the establishment of the intravascular metastatic niche. To understand whether platelet aggregation generally is critical for creating a metastatic niche or whether TXA\(_2\) signaling is more
In this paper we have provided evidence that aspirin reduces metastasis through the inhibition of platelet COX-1 and its product TXA2. Inhibition of COX-1 activity or TXA2 signaling alone by pharmacological or genetic means was sufficient to reduce metastasis in a range of models. This novel finding directly implicates the activity of COX-1/TXA2 in platelets before and during the intravascular transit of tumor cells, while it is not necessary for the persistent growth of the metastatic lung nodules. The inhibition of TXA2 in platelets supports the metastatic growth of tumor cells (Figure 12C), compatible with a functional COX-1/TXA2 pathway in platelets. Unlike aspirin, clopidogrel and epifibatide did not affect the early persistence of B16F10 melanoma cells in the lungs (Figure 12, D and E), suggesting that TXA2 signaling in the context of platelet aggregation is essential for the establishment of the early metastatic niche.

All together our data describe a signaling network centered on platelet-derived TXA2 that can be inhibited by aspirin treatment, leading to a reduced seeding efficiency and metastasis (Figure 13).
Aspirin has distinctive pharmacological properties at different doses, mainly derived from the differential inhibition of COXs in different body compartments. The antimetastatic effect of aspirin was seen at doses that inhibited COX-1/TXA\textsubscript{2}, whereas the inhibition of COX-2/PGE\textsubscript{2} alone was not sufficient, COX-1/TXA\textsubscript{2} in platelets impairs multiple consecutive steps of the hematogenous transit of tumor cells, leading to the reduction of tumor cells in the lung vasculature. Thus, COX-1 activity and TXA\textsubscript{2} production in platelets contribute to the generation of a permissive early metastatic niche (Figure 13).
Figure 10. TXA2 from platelets mediates the generation of the prometastatic intravascular niche. (A–C) MIP (median filter) of 3D confocal stacks of tumor cells (B16F10-CMAC, white) and platelets (Pits-PKH26, red) in lungs of platelet-depleted Cx3cr1gfp/+ mice (A) and quantification of the number (B) and volume (C) of clots per tumor cell (n = 3), at 8 hours after injection of tumor cells and COX-1+/+ or COX-1–/– platelets. Scale bar: 10 μm. (D–F) MIP (median filter) of 3D confocal stacks of lung sections labeled for E-selectin (green) and VCAM-1 (magenta) (D), number of tumor cells associated with activated endothelial cells (%) (E), and fluorescence intensity of E-selectin or VCAM-1 (F) (n = 3) in lung sections from platelet-depleted Cx3cr1gfp/+ mice injected with tumor cells and COX-1+/+ or COX-1–/– platelets. Scale bar: 50 μm. (G and H) MIP of 3D confocal stacks (×20, top row) and surface reconstruction (bottom row) of tumor cells (B16F10-CMAC, white), platelets (Pits-PKH26, magenta), and Cx3CR1+ monocytes/macrophages (GFP, green) (G) and quantification of the volume of monocyte/macrophage clusters (H) (n = 3) in whole lungs of platelet-depleted Cx3cr1gfp/+ mice injected with tumor cells and COX-1+/+ or COX-1–/– platelets. Scale bars: 50 μm. Data are represented as mean + SD. Unpaired t test, 2-tailed. *0.01 < P ≤ 0.05; ***P ≤ 0.001.
suggesting a prominence of COX-1 rather than COX-2 in the metastatic process. We exclude COX-independent targets (57) since analogous results were obtained with inhibitors of other steps in the COX pathway and in COX-1−/− mice. The antimetastatic effect of aspirin was seen in low- and medium-dose trials (75–300 mg/d), and increased doses did not show additional benefit (23), consistent with platelet COX-1 as the main target for the antimetastatic effect of aspirin. To the best of our knowledge, COX-1 has been previously implicated only marginally in the development of metastasis (58). COX-1 can be expressed by a variety of cell types (21). Reinfusion of platelets in platelet-depleted mice only restored metastasis if the platelets contained active COX-1, showing that it is the platelet supply of COX-1 that is essential to metastasis.

Further, although COX-1 can generate a variety of active prostaglandins, the reduction of TXA₂ is responsible for the antimetastatic effect of aspirin. Infusion of a synthetic analog of TXA₂ restored the metastatic phenotype during aspirin treatment. Platelets aggregate on the surface of tumor cells and function as circulating reservoirs of TXA₂. Autocrine TXA₂ signaling in platelets further enhances their aggregation on tumor cells, which supports metastasis (8, 26, 45). Additionally, paracrine TXA₂ signaling generates a favorable environment for tumor cell seeding through vascular constriction and induction of E-selectin and VCAM-1 through the TP receptor on endothelial cells (59, 60). Cytokines released from intracellular granules of activated platelets also induce endothelial cell activation (61). Endothelial activation correlates with tumor cell survival within the lung vasculature (32), and E-selectin and VCAM-1 might facilitate tumor cell adherence to the endothelium directly (62) or via bound platelets (63). We demonstrated enhanced adhesion of tumor cells to an LMVEC monolayer in the presence of platelets, analogous to the results in vivo. Concomitantly, endothelial activation facilitates the homing and retention of metastasis-promoting monocytes/macrophages in proximity to the tumor cells (32, 61). Monocyte chemoattractant protein-1 (CCL2/MCP-1) and CCL5 release by endothelial cells following TXA₂ signaling might amplify recruitment (29, 64). Altogether, local release of TXA₂ leads to the formation of hematogenous microemboli with metastatic properties. The recruitment of monocytes/macrophages was also reduced by aspirin at the level of the premetastatic niche, leading to reduced lung seeding. These data support the notion that cancer-induced thrombosis via the COX-1/TXA₂ pathway plays a central role in the conditioning of metastatic sites both before and after the arrival of CTCs (27).

The inhibition of COX-2 decreases metastasis in some models (10, 11) but not others (12). In our experiments, NS-398 did not reduce seeding of B16F10- and 4T1-derived lung metastasis, but it decreased the size of metastatic lung nodules from B16F10 cells, consistent with COX-2 enhancing proliferation and immune evasion in experimental models (65, 66). We noted that inhibition of COX-2 significantly inhibited metastasis by one colorectal cancer cell line, MC-38-GFP. Some colorectal cancers depend on COX-2 for progression (66), and we confirmed that MC-38 cells express much higher levels of COX-2 than B16F10 cells (S. Lucotti, unpublished observations). Thus, the sensitivity to COX-2 inhibition might be indicated by COX-2 expression in cancer cells (67).

In contrast, our data point to COX-1 inhibitors reducing metastasis through a microenvironment-centered mechanism. COX-1 inhibition was effective on cell lines regardless of their COX-1 expression (S. Lucotti, unpublished observations), and COX-1−/− mice had reduced metastasis, suggesting that aspirin has an antimetastatic effect independent of tumor cell expression of COX-1. Using Oncomine gene expression data we found that COX-1 expression in the primary tumor did not correlate with risk of metastatic cancer nor with the antimetastatic effect of aspirin.
However, aspirin significantly increases the risk of severe gastrointestinal symptoms and complications, especially over long-term use. Our data, together with previous clinical trials (71–73), suggest that selective TXA2 inhibitors such as picotamide might present an alternative to target platelet TXA2 while sparing other gastroprotective COX-1 products (i.e., PGI2), and thus might be a safer therapeutic option for the prevention of metastatic disease.

Methods

Animals. C57BL/6 (C57BL/6J), BALB/c (BALB/cAnNCrl), and SCID (CB17/Prkdcscid/Prkdcscid/Jcr) mice were purchased from Charles River Laboratories and Cx3cr1 gfp/+ mice (B6.129P-Cx3cr1tm1Litt/J) from The Jackson Laboratory (49). COX-1 −/− mice (74) were provided by TDW and JAM. Seven- to ten-week-old female mice were used for experiments involving drug treatment and/or tumor cell injection, while older naive mice with a C57BL/6 background were used for blood withdrawal and platelet isolation. Drugs were administered through drinking water, given ad libitum and changed every second day.

Cell lines and staining. B16F10 murine melanoma cells (a gift from John L. Francis, Center for Thrombosis Research, Florida Hospital, Orlando, Florida, USA; ref. 75) were cultured in RPMI 1640 medium (Sigma-Aldrich), 4T1/4T1-GFP murine breast cancer cells, MC-38-GFP murine colorectal cancer cells, and MDA-MB-231-CFP human breast cancer cells (ATCC) were cultured in DMEM (Sigma-Aldrich) in a 5% CO2 humidified atmosphere at 37°C. Media were supplemented with 10% heat-inactivated FBS (Gibco), 2 mM L-glutamine, 25 mM HEPES, 50 U/ml penicillin, and 5 μg/ml streptomycin (Ther-
Eptifibatide (Sigma-Aldrich) was resuspended in 100% ethanol was delivered in saline at 10 mg/kg/d through i.p. injection (56). Clopidogrel [(±)-Clopidogrel (hydrochloride), Cayman Chemical] dissolved in DMSO was resuspended at 12 mg/l in drinking water supplemented with 0.2% (vol/vol) polyethylene glycol 200 (PEG200) and 0.01% (vol/vol) Tween-20. Vapiprost (Vapiprost hydrochloride, Santa Cruz Biotechnology) dissolved in sterile water was resuspended in drinking water at 20 mg/l. All drinking water contained 2% wt/vol sucrose (Sigma-Aldrich). Picotamide (PICO; Abcam) dissolved in 100% ethanol (Sigma-Aldrich) was resuspended in drinking water at 30 mg/l. U46619 (Cayman Chemical) was dissolved in 0.20% wt/vol BSA). NS-398 (Cayman Chemical) dissolved in DMSO (Sigma-Aldrich) was resuspended at 24 mg/l in drinking water supplemented with 0.01% (vol/vol) Tween-20 (both from Sigma-Aldrich) (77). NS-398 (Cayman Chemical) dissolved in DMSO (Sigma-Aldrich) was resuspended at 12 mg/l in drinking water supplemented with 0.9% wt/vol sodium chloride (Sigma-Aldrich) (77). Picotamide (PICO; Abcam) dissolved in 100% ethanol (Sigma-Aldrich) was resuspended in drinking water at 30 mg/l U46619 (Cayman Chemical) was diluted in DMSO and delivered at 50 μg/kg through a 180-mg/l aspirin solution. Vapiprost (Vapiprost hydrochloride, Santa Cruz Biotechnology) dissolved in sterile water was resuspended in drinking water at 20 mg/l. All drinking water contained 2% wt/vol sucrose (Sigma-Aldrich). Clopidogrel [(2)-Clopidogrel (hydrochloride), Cayman Chemical] dissolved in 100% ethanol was delivered in saline at 10 mg/kg/d through i.p. injection (56). Eptifibatide (Sigma-Aldrich) was resuspended in sterile water and delivered in saline at 0.5 mg/kg/d through i.p. injection (78).

Isolation and staining of platelets. After sacrifice with an overdose of pentobarbital (665 mg/kg, i.p., or 332.5 mg/kg, i.v.), blood was collected from mice by cardiac puncture in syringes containing 3.2% (wt/vol) sodium citrate (Thermo Fisher Scientific) or ACD buffer (83 mM Na,C2H4O7, 111 mM dextrose, 71 mM citric acid) (Sigma-Aldrich and Fisher Thermo Scientific), at 1:10 vol/vol ratio to blood.

To test aggregation, citrated blood was diluted 1:2 with modified Tyrode’s-HEPES (MTH) buffer (134 mM NaCl, 0.3 mM NaHPO4·2H2O, 3 mM KCl, 5 mM HEPES, 5 mM dextrose, 2 mM MgCl2) (Sigma-Aldrich and Fisher Scientific) or 0.05% trypsin-EDTA solution (all other cell lines) (Sigma-Aldrich). LMVECs were used within 10 and tumor cells within 20 passages and routinely tested for mycoplasma contamination (MycopAlert Mycoplasma Detection Kit, Lonza Group Ltd.). Exponentially growing B16F10 cells (50%–60% confluence) were stained with 12.5 μM solution of CellTracker Blue CMAC, Orange CMRA, or Green CMFDA dye (Thermo Fisher Scientific), following the manufacturer’s instructions.

Drug formulation for animal studies. Aspirin (ASA), purchased as DL-lysine acetylsalicylate (Aspégic injectable, Sanofi Aventis), was dissolved in sterile deionized water and resuspended in drinking water at 30 mg/l (low) (37), 180 mg/l (medium) (38), or 625 mg/l (high) (8). SC-560 (Cayman Chemical) dissolved in DMSO was resuspended at 24 mg/l in drinking water supplemented with 0.2% (vol/vol) BSA, and 1 mM EGTA) and centrifuged at 1300 g for 2 minutes at room temperature, and the supernatant was collected (platelet-poor plasma [PPP]). The remaining pellet was centrifuged at 12,000 g for 2 minutes at room temperature, and the supernatant was collected (platelet-rich plasma [PRP]).

To prepare washed platelets, PRP was diluted with washing buffer (10% MTH vol/vol in dH2O, 0.10% wt/vol NaHCO3, 0.20% wt/vol BSA, and 1 mM EGTA) and centrifuged at 1300 g for 10 minutes. The platelet pellet was washed twice with washing buffer containing 0.25 mM PGE1. Platelets were counted in a Coulter counter (Beckman; 50-μm aperture tube, 3–30 fl particles). Washed platelets (8 × 10⁷ cells/μl) were stained with PKH26 (Sigma-Aldrich) and readjusted to the required concentration in PPP or resuspension buffer (10% MTH vol/vol in dH2O, 0.10% wt/vol NaHCO3, and 0.20% wt/vol BSA).

Platelet aggregation. Platelet aggregation was evaluated as previously described (79). Briefly, citrated PRP was incubated with agonists arachidonic acid (1 μM; Sigma-Aldrich), U46619 (0.3 μM; Tocris), and ADP (1 M; ChronoLog) or their vehicles in half-area-96-well microtiter plates for 5 minutes at 37°C under 1 mm orbital shaking (Infinite m200 plate reader, Tecan). Aggregated PRP (8 × 10⁵ cells/μl) was analyzed with a FACSCalibur flow cytometer (BD Biosciences). Beads (FL1/SSC-H) were gated and platelets (FL4-H/SSC-H) were acquired until the count of 100 beads was reached. The total number of single platelets was calculated using FlowJo software.

**Figure 13. Platelet-derived TXA2 promotes metastasis by generating a permissive intravascular metastatic niche.** Model of metastasis promotion by TXA2, derived from COX-1 activity in platelets. The aggregation of platelets on tumor cells stimulates the aspirin-sensitive de novo synthesis of TXA2, which enhances the expansion of clots on tumor cells and leads to further TXA2 synthesis. Concomitantly, TXA2-TP interaction induces the contraction of vascular smooth muscle cells, the activation of endothelial cells, and the recruitment of monocytes/macrophages to tumor cells, providing a permissive niche for metastasis seeding.
Depletion of the single-platelet population is representative of platelet aggregation, and can be visualized through the appearance of a comet tail of platelet aggregates (79).

*Ex vivo platelet aggregation on tumor cells.* CFM-DMA-stained B16F10 cells were seeded at 10° cells per well in collagen I-coated multichambers (BD Biosciences). The following day, 30 × 10° PKH26-stained platelets were added together with vehicle or drugs. After 2 hours, cells were fixed with 2% paraformaldehyde (PFA) in PBS and mounted with Vectashield mounting medium containing DAPI (Vector Laboratories). Tumor cells and platelets were pretreated with vehicle or drugs for 2 hours at 37°C or 30 minutes at 30°C, respectively, washed twice with PBS or washing buffer, and coincubated.

**Experimental lung metastasis assay.** B16F10 (2.5 × 10°) and MC-38-GFP (3.0 × 10°) cells were injected i.v. into C57BL/6 mice, 4T1 (1.5 × 10°) into BALB/c mice, and MDA-MB-231-CFP (1 × 10°) into SCID mice. R300 antibody (0.5 mg/kg; Emfret) for platelet depletion or isotype control (C301, Emfret) was injected i.p. 24 hours before i.v. injection of tumor cells and PPP (<1 × 10° platelets), PRP, or platelets (6 × 10° platelets). After 2 weeks (4T1 cells), 3 weeks (B16F10 and MC-38-GFP cells), or 4 weeks (MDA-MB-231-CFP cells), mice were anesthetized (pentobarbital, 70 mg/kg, i.p.) and their lungs artificially ventilated through a tracheotomy. After sacrifice, lungs were perfused through the pulmonary artery with Krebs-Ringer buffer (KRB) (4.74 mM KCl, 1.17 mM MgSO4·7H2O, 1.27 mM CaCl2·2H2O, 1.18 mM KH2PO4, 118.4 mM NaCl, 24.87 mM NaHCO3, 10 mM dextrose, 5% wt/vol dextan) (Sigma-Aldrich or Thermo Fisher Scientific). After clearance of blood, lungs were immersed in 10% neutral buffered formalin (Sigma-Aldrich). Metastatic lung nodules were visually counted (B16F10, MC-38-GFP, and 4T1 cells) or assessed by MRI scan (MDA-MB-231-CFP cells). Lobes were embedded in paraffin, and 5-μm sections were stained by H&E.

**MRI scan of lungs.** MRI on formalin-fixed lungs embedded in 4% agarose was performed at 4.7 T or 7.0 T (VNMRS, Agilent) using a 25-mm-inner-diameter quadrature birdcage coil (Rapid). T2-weighted fast spin echo 3D scan was acquired (echo spacing 9.35 ms, echo train length 8, effective echo time [TE] 37.41 ms, repetition time [TR] 200 ms) with a field of view (FOV) of 32 × 32 × 32 mm° to ensure complete coverage of the coil (and sample). Scan time was approximately 27 minutes per sample for an isotropic resolution of 125 μm. Ten samples were queued for unsupervised MRI measurement using an in-house-developed care system utilizing a stepper motor driven by an Arduino controller (http://www.arduino.cc). Tumor burden was quantified by manual segmentation via ImageJ (version 1.46r, NIH) and itk-SNAP software (version 3.6.0) (80).

**Ex vivo whole lung imaging assay.** CMAC-stained B16F10 cells (5 × 10°) and PKH26-stained platelets (9 × 10°) were injected into opposite tail veins of Cx3cr1gfp/ mice. After 8 or 24 hours, isolated lungs were placed in a specially designed chamber with a coverslip glass (0.16–0.19 mm thick) at its bottom. To visualize lung endothelium, anti-CD31-PE antibody (50 μg/kg; 102408, BioLegend) was injected in the vena cava 5 minutes before sacrifice, followed by vena cava ligation. Lungs were inflated with 0.5 ml of air and remained inflated during the imaging (27, 31, 81). Tumor cell extravasation was evaluated visually from microscopic FOV or through reconstruction of tumor cells and vessel surface with Imaris software (versions 8.2 and 9, Bitplane). The size of platelet microlots and monocyte/macrophage clusters was calculated through IM-LAB (R2017a) code written in-house.
PGE, was assayed through a PGE₂ Metabolite EIA kit (PGE₂M, Cayman Chemical), which measures 13,14-dihydro-15-keto-PGA₂ and 13,14-dihydro-15-keto-PGE₂ metabolites.

**Measurement of urinary salicylic acid.** Urine was collected from restrained C57BL/6 mice 2 weeks after iv. injection of B16F10 and supplemented with indomethacin (10 μg/ml in DMSO; Sigma-Aldrich). Urine was centrifuged at 10,000 g for 15 minutes at 4°C. Five microliters of urine was mixed with 50 μl 6-methoxysalicylate (internal standard, 10 μM) and 1 ml formic acid (10 mM). To measure salicylic acid (SUA), a 5-μl sample was injected onto the HPLC (Waters 2695) equipped with a Micromass Quattro Micro Mass Spectrometer (Separation was achieved using a Kinetex XB (2.6 μm, 2.1 × 50 mm) column maintained at 35°C with eluent A (10 mM formic acid) and eluent B (acetonitrile), using a flow rate of 0.25 ml/min and a gradient of 8%-50% B over 4 minutes. SUA was detected using electrospray in negative mode with tandem mass spectrometry with a capillary voltage of 1.2 V at 194–150 (cone voltage 20 V) and internal standard at 166.9–123 (cone voltage 20 V). Concentrations were calibrated against SUA [N-(2-hydroxybenzoyl)glycine, Apollo Scientific].

**Tumor cell adhesion assay under flow.** A flow-based assay coupled to live cell imaging was used, as described previously (82). 1.5 × 10⁴ LMVECs were seeded in μ-Slide IV (Ibidi) and grown to confluence. LMVECs, platelets, and tumor cells were pretreated with vehicle, aspirin (medium dose), SC-560, or NS-398 for 2 hours (LMVECs and 10 μg/ml in DMSO; Sigma-Aldrich). Urine was centrifuged at 10,000 g for 15 minutes at 4°C. Five microliters of urine was mixed with 50 μl 6-methoxysalicylate (internal standard, 10 μM) and 1 ml formic acid (10 mM). To measure salicylic acid (SUA), a 5-μl sample was injected onto the HPLC (Waters 2695) equipped with a Micromass Quattro Micro Mass Spectrometer (Separation was achieved using a Kinetex XB (2.6 μm, 2.1 × 50 mm) column maintained at 35°C with eluent A (10 mM formic acid) and eluent B (acetonitrile), using a flow rate of 0.25 ml/min and a gradient of 8%-50% B over 4 minutes. SUA was detected using electrospray in negative mode with tandem mass spectrometry with a capillary voltage of 1.2 V at 194–150 (cone voltage 20 V) and internal standard at 166.9–123 (cone voltage 20 V). Concentrations were calibrated against SUA [N-(2-hydroxybenzoyl)glycine, Apollo Scientific].

**Tumor cell adhesion assay under flow.** A flow-based assay coupled to live cell imaging was used, as described previously (82). 1.5 × 10⁴ LMVECs were seeded in μ-Slide IV (Ibidi) and grown to confluence. LMVECs, platelets, and tumor cells were pretreated with vehicle, aspirin (medium dose), SC-560, or NS-398 for 2 hours (LMVECs and 10 μg/ml in DMSO; Sigma-Aldrich). Urine was centrifuged at 10,000 g for 15 minutes at 4°C. Five microliters of urine was mixed with 50 μl 6-methoxysalicylate (internal standard, 10 μM) and 1 ml formic acid (10 mM). To measure salicylic acid (SUA), a 5-μl sample was injected onto the HPLC (Waters 2695) equipped with a Micromass Quattro Micro Mass Spectrometer (Separation was achieved using a Kinetex XB (2.6 μm, 2.1 × 50 mm) column maintained at 35°C with eluent A (10 mM formic acid) and eluent B (acetonitrile), using a flow rate of 0.25 ml/min and a gradient of 8%-50% B over 4 minutes. SUA was detected using electrospray in negative mode with tandem mass spectrometry with a capillary voltage of 1.2 V at 194–150 (cone voltage 20 V) and internal standard at 166.9–123 (cone voltage 20 V). Concentrations were calibrated against SUA [N-(2-hydroxybenzoyl)glycine, Apollo Scientific].

**Immunofluorescence.** Lungs were perfused with ice-cold PFA 4% and stored in sucrose 25% (Sigma-Aldrich) at 4°C for 2 days. Eighteen-micrometer sections (cryostat microtome, Bright) from snap-frozen lungs were stained for E-selectin (MAI-06506, Thermo Fisher Scientific), VCAM-1 (CBL1300, Millipore), and vWF (ab11713, Abcam) using a TSA biotin amplification system (PerkinElmer).

**Confocal microscopy.** Z-stack images were acquired with an inverted confocal microscope (LSM-710 and LSM-880, Zeiss) equipped with a Plan-Apochromat 20×/0.8 M27 objective. DAPI/CMAC (excitation, 405 nm; emission, 410–513 nm), GFP/Alexa Fluor 488/CMFDA (excitation, 488 nm; emission, 490–653 nm), PE/CMRA (excitation, 543 nm; emission, 548–692 nm), PKH26 (excitation, 561 nm; emission, 568–735 nm), and Alexa Fluor 633 (excitation, 633 nm; emission, 638–747 nm) were detected via a photomultiplier tube array (DAPI, CMAC, 4T1-GFP, Alexa Fluor 488, CMFDA, CMRA, PKH26, Alexa Fluor 633) or a gallium arsenide phosphide (GaAsP) array (PE, Cx.CR1-GFP). Channels were acquired sequentially to minimize bleed-through of emitted light. Stacks of 15-40 slices at 1- to 2-μm intervals from random FOV or tile scans of whole left lung (x10 or x20) were acquired.

**Statistics.** Statistical analysis was performed with GraphPad Prism (version 5.02). D’Agostino and Pearson omnibus normality test was applied to assess data distribution. For normally distributed data, unpaired t test (2-tailed) or 1-way ANOVA with Tukey’s test or Pearson’s test was used. For non-normally distributed data, Mann-Whitney test, Kruskal-Wallis with Dunn’s multiple-comparisons post hoc test, or Spearman’s test was used. Outliers were identified through Grubbs’s test (α = 0.05, GraphPad QuickCalc outlier calculator) and excluded. Differences were considered significant with a P value lower than 0.05.

**Study approval.** Animal procedures were performed in accordance with UK Animal law (Scientific Procedures Act 1986), including local ethics approval at the University of Oxford under project license 30/3413.

**Author contributions**

This project was conceived by SL, AMGB, and RJM with the methodology developed by SL, CC, MS, AMGB, ALG, PDA, SS, TDW, AJR, and RJM. The investigations were performed by SL, CC, MS, AMGB, ALG, BM, and KW. Software was developed by PDA and resources provided by PDA, SS, JAW, TDW, AJR, and RJM. Supervision of the project was provided by AMGB, TDW, AJR, and RJM. The original draft was written by SL and RJM.

**Acknowledgments**

We thank Graham Brown and Rhodri Wilson for expert advice and support with microscopy, Michael Stratford for the SUA measurement, and Andrew Worth for cell sorting. We also thank Paul Kincbes for developing MRI scans and Stuart Gilchrist and John Beech for developing the robot carriage system. RJM is funded by Cancer Research UK grant A1731. SL was the recipient of a Cancer Research UK Oxford Centre DPhil Prize Studentship (BBR17W00).
