The endogenous cannabinoid system protects against colonic inflammation

Federico Massa, … , Martin Storr, Beat Lutz

Excessive inflammatory responses can emerge as a potential danger for organisms' health. Physiological balance between pro- and anti-inflammatory processes constitutes an important feature of responses against harmful events. Here, we show that cannabinoid receptors type 1 (CB1) mediate intrinsic protective signals that counteract proinflammatory responses. Both intrarectal infusion of 2,4-dinitrobenzene sulfonic acid (DNBS) and oral administration of dextran sulfate sodium induced stronger inflammation in CB1-deficient mice (*\( \text{CB1}^{-/-} \)) than in wild-type littermates (*\( \text{CB1}^{+/+} \)). Treatment of wild-type mice with the specific CB1 antagonist *N*-piperidino-1-yl)-5-(4-chlorophenyl)-1-(2,4-dichlorophenyl)-4-methyl-pyrazole-3-carboxamide (SR141716A) mimicked the phenotype of *\( \text{CB1}^{-/-} \) mice, showing an acute requirement of CB1 receptors for protection from inflammation. Consistently, treatment with the cannabinoid receptor agonist *R*(-)-7-hydroxy-\( \Delta^6 \)-tetrahydrocannabinol-dimethylheptyl (HU210) or genetic ablation of the endocannabinoid-degrading enzyme fatty acid amide hydrolase (FAAH) resulted in protection against DNBS-induced colitis. Electrophysiological recordings from circular smooth muscle cells, performed 8 hours after DNBS treatment, revealed spontaneous oscillatory action potentials in *\( \text{CB1}^{-/-} \) but not in *\( \text{CB1}^{+/+} \) colons, indicating an early CB1-mediated control of inflammation-induced irritation of smooth muscle cells. DNBS treatment increased the percentage of myenteric neurons expressing CB1 receptors, suggesting an enhancement of cannabinoid signaling during colitis. Our results indicate that the endogenous cannabinoid system represents a promising therapeutic target for the treatment of intestinal disease conditions characterized by excessive inflammatory responses.

Excessive inflammatory responses can emerge as a potential danger for organisms’ health. Physiological balance between pro- and anti-inflammatory processes constitutes an important feature of responses against harmful events. Here, we show that cannabinoid receptors type 1 (CB1) mediate intrinsic protective signals that counteract proinflammatory responses. Both intrarectal infusion of 2,4-dinitrobenzene sulfonic acid (DNBS) and oral administration of dextrane sulfate sodium induced stronger inflammation in CB1-deficient mice (CB1−/−) than in wild-type littermates (CB1+/+). Treatment of wild-type mice with the specific CB1 antagonist N-(piperidino-1-yl)-5-(4-chlorophenyl)-1-(2,4-dichlorophenyl)-4-methyl-pyrazole-3-carboxamide (SR141716A) mimicked the phenotype of CB1−/− mice, showing an acute requirement of CB1 receptors for protection from inflammation. Consistently, treatment with the cannabinoid receptor agonist R−(−)-7-hydroxy-Δ⁶-tetra-hydrocannabinol-dimethylheptyl (HU210) or genetic ablation of the endocannabinoid-degrading enzyme fatty acid amide hydrolase (FAAH) resulted in protection against DNBS-induced colitis. Electrophysiological recordings from circular smooth muscle cells, performed 8 hours after DNBS treatment, revealed spontaneous oscillatory action potentials in CB1−/− but not in CB1+/+ colons, indicating an early CB1-mediated control of inflammation-induced irritation of smooth muscle cells. DNBS treatment increased the percentage of myenteric neurons expressing CB1 receptors, suggesting an enhancement of cannabinoid signaling during colitis. Our results indicate that the endogenous cannabinoid system represents a promising therapeutic target for the treatment of intestinal disease conditions characterized by excessive inflammatory responses.

Introduction

Colon pathologies span a wide range of different conditions, including frankly inflammatory bowel diseases (ulcerative colitis and Crohn disease) and so-called functional bowel diseases (e.g., irritable bowel syndrome), and represent an important and widespread health problem in modern society (1, 2). The occurrence of an enteric infection, trauma, or inflammation has been suggested to be related to the initiation of these diseases (2, 3). During the last decade, several experimental animal models of inflammatory bowel diseases have been developed to define the different components of the pathophysiological processes that characterize these disorders. Among these models, the intrarectal administration of 2,4-dinitrobenzene sulfonic acid (DNBS) and the oral administration of dextrane sulfate sodium (DSS) have been extensively used to study the mechanisms of colonic inflammation and to test anti-inflammatory drugs (4, 5). Infections, traumata, or chemical insults are believed to induce several cellular reactions, which eventually lead to an inflammatory status of the colon. At the same time, however, protective mechanisms aimed at preventing the pathological outcome of proinflammatory insults are also induced. Hence, the overall balance between pro- and anti-inflammatory mechanisms is likely to determine the progression and severity of colitis. A better understanding of intrinsic mechanisms that protect against inflammation would provide an effective starting point for development of novel therapeutic treatments.

The major active constituent of the plant Cannabis sativa (marijuana), Δ⁶-tetrahydrocannabinol, and a variety of natural and synthetic cannabinoids have been shown to possess antinociceptive and anti-inflammatory activities (6–8). For millennia, Cannabis preparations have been used in folk medicine for the treatment of a wide variety of disorders, including those affecting the gastrointestinal tract (9). A century ago, extracts of Cannabis were used in the US to treat gastrointestinal pain of different origins, gastroenteritis, and diarrhea. There are also anecdotal reports suggesting that marijuana may be effective in alleviating symptoms of Crohn disease (10). Most of the biological actions of cannabinoids are mediated by two types of cannabinoid receptors, CB1 and CB2, both coupled to G proteins (11–13). Endogenous ligands for cannabinoid receptors (endocannabinoids) such as the agonists anandamide and 2-arachidonoyl-glycerol (2-AG) are lipidic messengers derived from arachidonic acid (11–13). After synthesis in the cell membrane, release into extracellular space, and action at cannabinoid receptors, endocannabinoids are

Nonstandard abbreviations used: 2-arachidonoyl-glycerol (2-AG); cannabinoid receptor type 1 (CB1); cannabinoid receptor type 2 (CB2); dextrane sulfate sodium (DSS); 2,4-dinitrobenzene sulfonic acid (DNBS); fatty acid amide hydrolase (FAAH); hexa-decyl-trimethyl-ammonium bromide (HTAB); in situ hybridization (ISH); myeloperoxidase (MPO); N-(piperidino-1-yl)-5-(4-chlorophenyl)-1-(2,4-dichlorophenyl)-4-methyl-pyrazole-3-carboxamide (SR141716A); preproenkephalin (Enk); resting membrane potential (RMP).

rapidly inactivated by cellular uptake and degradation mediated by specific enzymes, among which the best-characterized is fatty acid amide hydrolase (FAAH) (12–14). The discovery of endocannabinoids and the characterization of the mechanisms for their synthesis and degradation evidenced the existence of the endogenous cannabinoid system, which exerts many physiological functions. Functional CB1 receptors are present on enteric neurons (15–20), and the gastrointestinal tract produces at least two endocannabinoids, namely anandamide and 2-AG (8, 20, 21).

In fact, the endogenous cannabinoid system plays a role in the control of various functions, including gut protection, intestinal motility, and secretion (8). In the present investigation, we examined the role of the endogenous cannabinoid system after inflammatory insults in the colon and show that this system provides intrinsic protection against colonic inflammation.

Methods

Animals. Eight- to ten-week-old CB1-deficient (CB1−/−) and FAAH-deficient (FAAH−/−) female mice and corresponding wild-type littermates were used for experiments (22, 23). Mice were in mixed genetic background, with a predominant C57BL/6N contribution (five backcrosses for both mutant lines). Eight- to ten-week-old female C57BL/6N mice were purchased from Charles River Wiga GmbH (Sulzfeld, Germany). Mice were housed under standard conditions and supplied with drinking water and food ad libitum. All animal procedures complied with the guidelines for care and use of laboratory animals of the government of the state of Bavaria, Germany.

Materials. DNBS was purchased from ICN Biomedicals GmbH (Eschwege, Germany), DSS from Sigma-Aldrich (Taufkirchen, Germany), and (R)-(-)-7-hydroxy-\(\Delta^6\)-tetra-hydrocannabinol-dimethylheptyl (HU210) from Tochrus Cookson Ltd. (Bristol, United Kingdom). \(N\)-(piperidino-1-yl)-5-(4-chlorophenyl)-1-(2,4-dichlorophenyl)-4-methyl-pyrazole-3-carboxamide (SR141716A) was a gift from the National Institute of Mental Health’s Chemical Synthesis and Drug Supply Program (USA).

Induction of colitis. After 36 hours of starving, colitis was induced by intrarectal administration of DNBS (5 mg per mouse) using a modification (24) of the method first described in rats (25). In pilot experiments, this dose of DNBS was found to induce reproducible colitis without mortality in heterozygous CB1−/− mice (data not shown). Briefly, mice were lightly anesthetized with isoflurane, and DNBS (5 mg in 100 \(\mu\)l of 50% ethanol) was infused into the rectum through a catheter (outer diameter 0.8 mm), inserted 4–5 cm proximally to the anus. Solvent alone (100 \(\mu\)l of 50% ethanol) was administered in control experiments. Colitis was also induced by oral administration of DSS (5% in drinking water for 7 days) as described in ref. 26.

Pharmacological treatments. Drugs were injected subcutaneously (20 ml/kg body weight) under light isoflurane anesthesia. SR141716A (3 mg/kg body weight) and HU210 (0.05 mg/kg body weight) were dissolved in vehicle solution (one drop of Tween-80 in 3 ml 2.5% dimethylsulfoxide in saline) and injected 30 minutes before and 24 hours and 48 hours after DNBS infusion. Vehicle solution was used in control experiments.

Evaluation of colonic damage. Mice were killed by cervical dislocation 3 days after DNBS treatment, unless otherwise specified, or 7 days after continuous DSS treatment. The colon was removed and rinsed gently with saline solution, then opened by longitudinal incision and examined immediately. Colonic damage was assessed by a semiquantitative scoring system originally established in rats (27) and adapted to mice for the present study. Morphology was scored according to the following scale: 0, no damage; 1, localized hyperemia without ulcers; 2, linear ulcers without significant inflammation; 3, one site of ulceration or inflammation; 4, two or more sites of ulceration or inflammation with a total extension less than 1 cm; 5, two or more sites of ulceration or inflammation with a total extension more than 1 cm longitudinally; 6–10, if damage covered more than 1 cm longitudinally, the score is increased by 1 for each additional 0.5 cm of damage. In the presence of diarrhea, the score is increased by 1.

Determination of tissue myeloperoxidase activity. Samples of colon were weighed, frozen, and processed for determination of myeloperoxidase (MPO) activity. MPO activity represents an index of neutrophil accumulation (28, 29). Tissue was suspended in hexadecyl-trimethyl-ammonium bromide (HTAB) buffer (0.5% HTAB [Sigma-Aldrich] in 50 mM potassium phosphate buffer, pH 6.0; 50 mg of tissue/ml) and disrupted using a homogenizer. HTAB is a detergent that releases MPO from the primary granules of neutrophils. After one freezing/thawing cycle of the homogenate and centrifugation (15–30 minutes, 16,000 g, 4°C), 0.1 ml of supernatant was added to 2.9 ml of 50 mM potassium phosphate buffer (pH 6.0) containing 0.167 mg/ml of O-dianisidine dichloride and 0.05% \(H_2O_2\). Absorbance was measured at 460 nm (Beckman 640U photometer; Beckman Coulter GmbH, Unterschleißheim, Germany). MPO was expressed in milliunits per gram of wet tissue, 1 unit being the quantity of enzyme able to convert 1 \(\mu\)mol of \(H_2O_2\) to water in 1 minute at room temperature. Units of MPO activity per minute were calculated from a standard curve using purified peroxidase enzyme (Sigma-Aldrich). As considerable variations in the magnitude of the MPO values were observed between batches of animals studied during a 12-month period, data for each experiment were normalized to the value obtained in control groups.

In situ hybridization and neuron counting. After isolation, the colons were snap-frozen on dry ice and stored at −80°C until sectioning. The colons were mounted on Tissue-Tek (Polysciences Europe GmbH, Eppelheim, Germany), and 20-μm-thick transverse sections were cut on a cryostat Microtome HM 560 (Microm International GmbH, Braunschweig, Germany). Sections were mounted onto frozen Superfrost Plus slides (Fisher Scientific GmbH, Hannover, Germany), dried on a 42°C warming plate, and stored at −20°C until use. \(\text{\textsuperscript{35}}S\)-labeled riboprobe for CB1 and preproenkephalin (Enk) were used for in situ hybridization (ISH). The probe for CB1 was generated as described previously (30, 31). The cDNA for the generation of the Enk riboprobe was synthesized by RT-PCR on whole mouse-brain RNA preparation, using the primers 5′-TGACACTGGAAATGTAAGGA and 5′-CACA-GACCTAAATACAGC, corresponding to bp 887–867, respectively, of GenBank accession no. M13227. ISH and subsequent exposure to photographic emulsion (Kodak NTB-2 [Sigma-Aldrich] diluted 1:1 in distilled water) were carried out as described in detail in ref. 30.

Parallel sections, adjacent to the ones used for ISH, were fixed for 1 hour in Carnoy solution and were stained with cuproinic blue (32) for total counts of myenteric neurons. The staining solution (0.3% cuproinic acid and 1 M MgCl\(_2\) in 0.025 M sodium acetate buffer, pH 5.6) was applied for 60 minutes at room temperature, and the sections were then rinsed in distilled water and placed in sodium acetate buffer (pH 5.6) containing 1 M MgCl\(_2\). Finally, sections were rinsed in distilled water, placed in ethanol and xylene, and then mounted in DPX.
(BDH Chemicals Ltd., Poole, United Kingdom). CB1-positive, Enk-positive, and cuprolinic blue-positive neurons (total population) were counted on four to six randomly chosen sections for each animal (three animals per group) by two independent observers blinded to animals’ treatment and genotype. On each section, the length of serosa was measured, and the average number of cells per millimeter of serosal length was calculated for each mouse. Data were expressed as percentage of control groups (untreated CB1+/+ mice).

Electrophysiological experiments. The colon was exposed by an abdominal midline incision. The complete large bowel was removed and placed into oxygenated Krebs solution of the following composition (in mM): NaCl 120.5, KCl 5.9, MgCl2 2.5, NaH2PO4 1.2, NaHCO3 15.5, CaCl2 2.5, glucose 11.5, pH 7.4. The colon was opened along the mesenteric border, washed of remaining fecal material, and pinned out in a Sylgard-lined dissecting dish (Dow Corning Corp., Midland, Michigan, USA) containing oxygenated Krebs solution. The distal colon was separated, and mucosa and submucosa were removed, resulting in sheets of tissue consisting of circular and longitudinal muscle layers, together with the attached myenteric plexus. The sheets of distal colon were pinned using 150–200 wolfram wire micropins (15–25 µm in thickness) to the Sylgard-based electrophysiological chamber with the circular muscle layer uppermost. Experiments with CB1–/– and wild-type littermates at the same time point after induction of inflammation were performed simultaneously in one electrophysiological chamber. The chamber was perfused (5 ml/min; Kwik-peristaltic-pump, World Precision Instruments Inc., Sarasota, Florida, USA) with pre-warmed (37°C) oxygenated (95% O2/5% CO2) Krebs solution. Tissues were allowed to equilibrate for 90–120 minutes before the start of the experiments. Capillary glass microelectrodes (borosilicate glass capillaries, 1.0 mm outer diameter × 0.58 mm inner diameter; Clark Electromedical Instruments, Edenbridge, United Kingdom) were made using a microelectrode puller (model P-97, 3-mm-wide filament; Sutter Instrument Co., Novato, California, USA), were filled with KCl (3 mM), and had resistances in the range 80–120 MΩ. Resting membrane potentials (RMPs) of circular smooth muscle cells were recorded against a ground Ag-AgCl electrode placed in the bath medium as described in detail in ref. 33. Membrane potentials were amplified (DUO 733 microelectrode amplifier; World Precision Instruments Inc.) and digitalized with an analog-to-digital converter (SCB-68 interface; National Instruments Corp., Austin, Texas, USA). Permanent recordings of membrane potentials were made on a personal computer running the LabVIEW 5.0 program (National Instruments Corp.).

Statistical analysis. Results are expressed as mean ± SEM and were compared using Student’s t test. P values less than 0.05 were considered statistically significant.

Results

Genetic and pharmacological blockade of CB1 signaling increases severity of induced colitis. In order to study the involvement of CB1 and the endogenous cannabinoid system in colon inflammation, we first used CB1-deficient mice in the DNBS model of colitis. Intrarectal administration of 100 µl of 50% ethanol did not induce detectable inflammation in CB1–/– nor in CB1+/+ mice, as macroscopically evaluated (data not shown). Conversely, after intrarectal administration of DNBS (5 mg per mouse), macroscopic evaluation of CB1–/– colons revealed stronger inflammation as compared with CB1+/+ mice (CB1+/+, 1.7 ± 0.2, vs. CB1–/–, 3.7 ± 0.3, P < 0.05; Figure 1A). MPO assay revealed that the degree of inflammation was higher in CB1–/– than in CB1+/+ mice (CB1+/+, 100% ± 37%, vs. CB1–/–, 230% ± 54%, P < 0.05; Figure 1B). Histological analysis confirmed these observations, showing no differ-

**Figure 1**  
DNBS- and DSS-induced colitis is worsened in CB1–/– and in SR141716A-treated (3 mg/kg) C57BL/6N mice. (A and B) Macroscopic score of colonic inflammation (A) and levels of MPO activity (B) in CB1+/+ and CB1–/– littermates. (C and D) Macroscopic score of colonic inflammation (C) and levels of MPO activity (D) in vehicle- and SR141716A-treated C57BL/6N mice. Data are means ± SEM.
ences between genotypes in untreated colons (Figure 2, A and B) and dramatically increased inflammatory signs in DNBS-treated CB1−/− as compared with CB1+/+ colons (Figure 2, C and D). In particular, a notable disruption of the epithelial structure with extensive hemorrhagic necrosis and infiltration of neutrophils into the mucosa was detected in CB1−/− colons, with acute inflammation extending into the submucosa and the muscle layer.

To further substantiate the general involvement of CB1 signaling in colon inflammation, we characterized the development of colitis in CB1-deficient mice subjected to oral DSS treatment (5% in drinking water) for 7 days. Macroscopic evaluation of CB1−/− colons revealed stronger inflammation as compared with CB1+/+ colons (Figure 1A). Macroscopic score in CB1−/− was more than twofold higher than in CB1+/+ mice (CB1+/+, 0.8 ± 0.2, vs. CB1−/−, 2.1 ± 0.4, P < 0.05). MPO assay showed that the degree of inflammation was higher in CB1−/− than in CB1+/+ mice, although the difference did not reach statistical significance (CB1+/+, 100% ± 14.9%, vs. CB1−/−, 423.5% ± 189.8%, P = 0.053; Figure 1B).

In order to check for the acute involvement of CB1 in protection against inflammation, we treated wild-type C57BL/6N mice with the specific CB1 antagonist SR141716A (3 mg/kg) 30 minutes before and 24 and 48 hours after intrarectal administration of DNBS. Treatment with SR141716A markedly reduced the levels of inflammation as compared with treatment with vehicle, as revealed by macroscopic scoring (vehicle, 3.7 ± 0.5, vs. SR141716A, 1.8 ± 0.3, P < 0.05; Figure 1B) and by MPO assay (vehicle, 100% ± 39%, vs. SR141716A, 5.4% ± 2.7%, P < 0.05; Figure 1D). Moreover, we analyzed the response to DNBS-induced inflammation in FAAH-deficient (FAAH−/−) mice, which are profoundly impaired in their ability to degrade anandamide (23). The macroscopic score in FAAH−/− mice was 2.0-fold lower than in FAAH+/+ littermates (FAAH+/+, 3.8 ± 0.8, vs. FAAH−/−, 1.9 ± 0.5, P < 0.05; Figure 3C). MPO assay confirmed that the degree of inflammation was higher in FAAH+/+ than in FAAH−/− mice (FAAH+/+, 100% ± 32%, vs. FAAH−/−, 22% ± 16%, P < 0.05; Figure 3D).

CB1 and Enk mRNA levels are upregulated in the colon after DNBS-induced inflammation. Using ISH, the levels of CB1 transcripts were evaluated at a single-cell resolution in colons of CB1−/− mice either in control conditions or 3 days after intrarectal administration of DNBS. In control colons, CB1 mRNA was predominantly expressed stimulation of cannabinoid receptors during inflammatory processes might decrease the level of inflammation. Therefore, we treated C57BL/6N wild-type mice with the potent cannabinoid agonist HU210 (0.05 mg/kg) 30 minutes before and 24 and 48 hours after intrarectal administration of DNBS. Treatment with HU210 markedly reduced the levels of inflammation as compared with treatment with vehicle, as revealed by macroscopic scoring (vehicle, 3.7 ± 0.5, vs. HU210, 1.8 ± 0.3, P < 0.05; Figure 3A) and by MPO assay (vehicle, 100% ± 39%, vs. HU210, 5.4% ± 2.7%, P < 0.05; Figure 3B). Moreover, we analyzed the response to DNBS-induced inflammation in FAAH-deficient (FAAH−/−) mice, which are profoundly impaired in their ability to degrade anandamide (23). The macroscopic score in FAAH−/− mice was 2.0-fold lower than in FAAH+/+ littermates (FAAH+/+, 3.8 ± 0.8, vs. FAAH−/−, 1.9 ± 0.5, P < 0.05; Figure 3C). MPO assay confirmed that the degree of inflammation was higher in FAAH+/+ than in FAAH−/− mice (FAAH+/+, 100% ± 32%, vs. FAAH−/−, 22% ± 16%, P < 0.05; Figure 3D).

CB1 and Enk mRNA levels are upregulated in the colon after DNBS-induced inflammation. Using ISH, the levels of CB1 transcripts were evaluated at a single-cell resolution in colons of CB1−/− mice either in control conditions or 3 days after intrarectal administration of DNBS. In control colons, CB1 mRNA was predominantly expressed...
in neurons belonging to the myenteric plexus (Figure 4A). After DNBS-induced inflammation, an increase in the number of CB1-expressing cells was observed (Figure 4B). Counting of single CB1-expressing cells confirmed this observation (untreated, 100% ± 17.5%, vs. treated, 205.2% ± 22.9%, *P* < 0.05; Figure 4C).

The endogenous opioidergic system was recently shown to participate in the protection against inflammation in the TNBS model of colitis through the activation of µ-opioid receptors (34). To test whether the protective functions of the endogenous cannabinoid system involve the activation of endogenous opioid signaling, we analyzed Enk mRNA–expressing neurons in untreated and DNBS-treated colons derived from both CB1+/+ and CB1–/– mice. In untreated colons, the number of cells expressing Enk was not different between genotypes (CB1+/+, 100% ± 18.9%, vs. CB1–/–, 109.3% ± 17.1%, *P* > 0.05; Figure 4, D and E). After DNBS treatment, the number of Enk-expressing cells was significantly increased in both CB1+/+ colons (249.0% ± 28.7%, *P* < 0.01 vs. untreated CB1+/+; Figure 4F) and CB1–/– colons (205.7% ± 27.9%, *P* < 0.05 vs. untreated CB1–/–; Figure 4H). After DNBS treatment, the number of Enk-expressing cells was significantly increased both in CB1+/+ colons (249.0% ± 28.7%, *P* < 0.01 vs. untreated CB1+/+; Figure 4F and H) and in CB1–/– colons (205.7% ± 27.9%, *P* < 0.05 vs. untreated CB1–/–; Figure 4, G and H).

Counts of myenteric neurons were carried out in parallel, on cuprolinic blue-stained sections adjacent to the ones used for ISH. Comparable numbers of neurons were shown per unit length of serosa in DNBS-treated versus untreated colons, as well as in CB1+/+ versus CB1–/– mice (untreated CB1+/+, 100% ± 5.1%; treated CB1+/+, 120.7% ± 11.6%; untreated CB1–/–, 97.8% ± 5.7%; treated CB1–/–, 109.2% ± 6.4%; *P* > 0.1 for all comparisons); thus, no overt changes were shown in overall neuronal populations.

**Figure 4**

Relative numbers of CB1- and Enk-expressing myenteric neurons are increased 3 days after DNBS treatment, as detected by ISH. (A and B) Micrographs showing CB1 mRNA in untreated (A) and in DNBS-treated (B) CB1+/+ mice. (C) Quantitative evaluation of CB1-expressing cells in the myenteric plexuses of DNBS-treated CB1+/+ mice (white bar, *n* = 3). (D–G) Micrographs showing Enk mRNA in untreated CB1+/+ (D), untreated CB1–/– (E), DNBS-treated CB1+/+ (F), and DNBS-treated CB1–/– (G) colons. (H) Quantitative evaluation of Enk-expressing cells in the myenteric plexuses of DNBS-treated CB1+/+ (white bar, *n* = 3) and CB1–/– (black bar, *n* = 3) mice. Values are means ± SEM. *P* < 0.05, **P* < 0.01 vs. respective untreated controls. Dotted lines, 100%. *n* = 3 per group. Arrows: CB1- and Enk-expressing cells. Scale bar: 100 µm.

**Time-course analysis of DNBS-induced colitis.** Three days after intrarectal administration of DNBS, inflammatory responses appear to be modulated by the endogenous cannabinoid system. This time point was chosen because maximal acute DNBS-induced inflammation has been reported in mice after 3 days (35). However, the involvement of CB1 at different stages of the inflammatory process is still an open question. Macroscopic scoring, MPO activ-
Intracellular recordings from circular smooth muscles in distal colon of CB1+/+ and CB1–/– littermates (Figure 5). On day 1, macroscopic inflammation was absent in mice at any time point after DNBS treatment or in mice (–51.1 ± 0.6 mV, –51.6 ± 0.9 mV, vs. CB1+/+, 100% ± 36%, vs. CB1–/–, 314% ± 105%, P < 0.05; day 3: CB1+/+, 3.2 ± 0.5, vs. CB1–/–, 4.8 ± 0.5, P < 0.05; Figure 5A), in MPO activity (day 2: CB1+/+, 100% ± 36%, vs. CB1–/–, 314% ± 105%, P < 0.05; day 3: CB1+/+, 100% ± 20%, vs. CB1–/–, 354% ± 163%, P < 0.05; Figure 5B), and in body-weight loss (day 2: CB1+/+, –3.8% ± 3.5%, vs. CB1–/–, –14.7% ± 2.0%, P < 0.05; Figure 5C). By contrast, on day 2 and day 3, significant differences were found in the analysis of macroscopic score (day 2: CB1+/+, 3.7 ± 0.3, vs. CB1–/–, 5.5 ± 0.2, P < 0.05; day 3: CB1+/+, 3.2 ± 0.5, vs. CB1–/–, 4.8 ± 0.5, P < 0.05; Figure 5A), in MPO activity (day 2: CB1+/+, 100% ± 36%, vs. CB1–/–, 314% ± 105%, P < 0.05; day 3: CB1+/+, 100% ± 20%, vs. CB1–/–, 354% ± 163%, P < 0.05; Figure 5B), and in body-weight loss (day 2: CB1+/+, –7.3% ± 1.6%, vs. CB1–/–, –14.1% ± 0.7%, P < 0.05; day 3: CB1+/+, –3.8% ± 3.5%, vs. CB1–/–, –14.7% ± 2.0%, P < 0.05; Figure 5C). Therefore, macroscopic inflammatory signs were stronger in CB1−/− already 24 hours after the inflammatory insult, whereas the effects of the lack of CB1 on MPO levels and body-weight loss required a longer period of time to become evident. Additionally, the regain of body weight of CB1+/+ mice on day 3 was absent in CB1−/− mice (Figure 5C), suggesting that CB1 might play a role in the recovery from colonic inflammation to reconstitute general health.

Electrophysiological analysis shows spontaneous oscillatory activities in CB1+/+ mice at early stages of colonic inflammation. Circular smooth muscle cells of uninflamed CB1+/+ mice displayed a stable RMP of −51.6 ± 0.9 mV (n = 4), which was not different from the RMP measured in CB1−/− mice (–51.1 ± 0.6 mV, n = 4, P > 0.05; Figure 6A). Additionally, 8 hours and 24 hours after DNBS treatment, RMP was not different between genotypes (8 hours: CB1+/+, –50.0 ± 1.4 mV, vs. CB1−/−, –51.3 ± 0.3 mV, n = 4, P > 0.05; Figure 6B; 24 hours: CB1+/+, –55.0 ± 1.2 mV, vs. CB1−/−, –53.4 ± 1.5 mV, n = 3, P > 0.05; Figure 6C). In both genotypes, RMP was not changed in the presence of atropine (1 µM), an inhibitor of cholinergic transmission (data not shown). After DNBS treatment, however, CB1−/− mice displayed spontaneous action potentials with a frequency of 26.8 ± 2.9 min−1 and an amplitude of 29.3 ± 2.6 mV 24 hours after initiation of inflammation (n = 5). These spontaneous action potentials were not observed in CB1+/+ mice at any time point after DNBS treatment or in untreated mice (Figure 6). The rhythmic action potentials were unchanged in the presence of atropine (1 µM) (data not shown).

Discussion

Upon inflammatory insults, several different cellular pathways are activated in the intestinal tract, leading to a pathological state (36). However, simultaneous protective mechanisms are also activated, and the balance between pro- and anti-inflammatory responses determines the outcome of the pathological processes (37).

In this study, we analyzed the involvement of the endogenous cannabinoid system in the development of experimental colitis in mice, induced by intrarectal DNBS treatment and oral DSS application. Genetic ablation of CB1 receptors rendered mice more sensitive to inflammatory insults, indicating a protective role of the CB1 receptors during inflammation. This protection was mediated by an acute activation of the endogenous cannabinoid system rather than being caused by developmental defects due to the lifelong absence of CB1 receptors, since pharmacological blockade of CB1 with the specific antagonist SR141716A led to a worsening of colitis that was similar to that observed in CB1-deficient mice. The involvement of the endogenous cannabinoid system in the modulation of the acute phase of DNBS-induced colitis is further supported by the increased levels of transcripts coding for CB1 in wild-type mice after induction of inflammation. By ISH experiments, the number of CB1-expressing cells was found to be significantly increased after inflammation, without any simultaneous significant increase of the total number of neurons. Thus, it appears that neurons that express undetectable or very low levels of CB1 receptor in basal conditions, start to express this receptor to enhance endocannabinoid signaling.

The protective role of the endogenous cannabinoid system was observed 24 hours after DNBS treatment and became more evident on day 2 and day 3. However, increased spontaneous spiking activity of smooth muscle cell membrane of DNBS-treated colon from CB1−/− mice was already visible 8 hours after DNBS treatment, indicating that inflammation-induced irritation of smooth muscle occurs at an earlier stage than in wild-type mice. This gives further support to the notion that the endogenous cannabinoid system is protective against inflammatory changes. These data indicate that the activation of CB1 and of the endogenous cannabinoid system is an early and important physiological step during self-protection of the colon against inflammation.

The occurrence of dysmotility in inflammatory diseases of the small or the large intestine is widely accepted. Contractility of smooth muscle to cholinergic or tachykinergic stimuli is increased in the early stages and decreased in the later stages of inflammation (38, 39), and contractility following electrical neuronal stimulation in the inflamed gut is increased (40). The electrophysiological changes in the distal colon, as used in this study, show increased smooth muscular excitability, leading to the occurrence of spontaneous spiking activity. This kind of irritation was recently described for guinea pig distal colonic neurons, leading to the suggestion that dysmotility in inflamed colon is due to a disruption of the afferent limb of the intrinsic motor reflexes (41). In these changes, the release of tachykinins from capsaicin-sensitive neurons might play a major role (42), whereas cholinergic mechanisms seem not to be involved. These observations are in good agreement with our results, suggesting a cholinergic-independent mechanism, since the spiking activi-
ty was not changed after atropine application. Consistent with this hypothesis, CB1 receptors, identified by immunohistochemistry on substance P–containing neurons (43), have been shown to be involved in the noncholinergic control of intestinal motility (44).

In the small intestine, an involvement of CB1 receptors in the control of intestinal motility during croton oil–induced inflammation was recently evidenced. Izzo et al. showed that pharmacological administration of cannabinoids is able to delay gastrointestinal transit in croton oil–treated mice (45). Increased levels of CB1 receptor expression in inflamed jejunum may contribute to this protective effect (45). However, this work was not able to reveal a physiological protective action of the endogenous cannabinoid system against enteritis, since administration of the CB1 antagonist SR141716A alone failed to specifically worsen inflammation-induced gut hypermotility. By applying genetic and pharmacological approaches, our present investigation extended the observations by Izzo et al. (45) to the large intestine and, using morphological criteria, MPO measurements, and electrophysiological recordings, included the determination of inflammatory responses in the absence of a functional endogenous cannabinoid system. Most importantly, we were able to clearly show a physiological protective role of the endogenous cannabinoid system against intestinal inflammation.

A protective role against colon inflammation was recently shown for the endogenous opioidergic system (34), and a cross-talk between endogenous cannabinoid and opioid systems has been proposed (46). We found that DNBS treatment increased the levels of mRNA encoding the endogenous opioid Enk in the colon. This increase was present in DNBS-treated colons of both genotypes, indicating that CB1 receptors are not necessary to induce the increase in Enk mRNA levels during inflammatory processes. However, these results do not exclude a possible cross-talk between the two protective endogenous systems, and further investigations are needed to clarify this issue.

FAAH is the major enzyme involved in the degradation of several bioactive fatty amides, in particular of anandamide (47), and its genetic deletion in mice leads to strongly decreased ability to degrade this endocannabinoid and to an increase of anandamide levels in several tissues (23). FAAH-deficient mice showed significant protection against DNBS treatment. Moreover, pharmacological stimulation of cannabinoid receptors with the potent agonist HU210 also induced a reduction of experimental colitis. Anandamide is believed to act not only through CB1 receptors, but also through other targets, including the peripheral cannabinoid receptor CB2 and the vanilloid receptor TRPV1 (48). On the other hand, HU210 is also able to stimulate CB2 (13). Therefore, it cannot be excluded that decreased inflammation in FAAH+/− mice and the anti-inflammatory actions of HU210 are due to the activation of other targets than CB1 receptors. However, our data from CB1+/− and SR141716A-treated mice clearly point to a central role of CB1 in the physiological control of colonic inflammation. A recent investigation showed that cholera toxin–induced accumulation of intestinal fluid in mice is modulated by activation of the endogenous cannabinoid system acting through CB1, but not through TRPV1 nor CB2, receptors (49). Moreover, CB1 receptors were also shown to modulate gastrointestinal motility during croton oil–induced inflammation in mice (45). However, conclusive results regarding the involvement of TRPV1 in protective signaling cascades after DNBS treatment should be possible using TRPV1-deficient mice.

The ability of cannabinoid receptor agonists to suppress peritoneal inflammation and to inhibit inflammation-induced gastrointestinal hypermotility when administered intracerebroventricularly has recently been shown (45, 50), indicating that cannabinoids may also act in the CNS to exert their anti-inflammatory activities. As we used systemic treatments and mutant mice bearing gene deletions in all cells of the body, we cannot exclude a central component of the anti-inflammatory effects of the endogenous cannabinoid system during DNBS-induced colitis. However, the early alterations in electrophysiological properties of inflamed CB1+− colons and the increased levels of CB1 mRNA in myenteric plexuses of DNBS-treated colons seem to point to an important, if not predominant, function of the endogenous cannabinoid system at peripheral sites. Use of central administration of drugs or, conversely, of cannabinoid agonists and antagonists unable to cross the blood-brain barrier, or the generation of conditional CB1 mutant mice with tissue-specific deletion of the gene, will help to clarify this important issue.

In conclusion, this study shows that the endogenous cannabinoid system is physiologically involved in the protection against excessive inflammation in the colon, both by dampening smooth muscular irritation caused by inflammation and by controlling cellular pathways leading to inflammatory responses. These results strongly suggest that modulation of the physiological activity of the endogenous cannabinoid system during colonic inflammation might be a promising therapeutic tool for the treatment of several diseases characterized by inflammation of the gastrointestinal tract.
