Article

Vaccines

A lack of relevant animal models has hampered preclinical screening and critical evaluation of the efficacy of human vaccines in vivo. Carcinoembryonic antigen–A2Kb (CEA–A2Kb) double transgenic mice provide a biologically relevant model for preclinical screening and critical evaluation of human CEA vaccine efficacy in vivo, particularly because such animals are peripherally tolerant of CEA. We established the utility of this model by demonstrating that an oral DNA minigene vaccine induces effective HLA-A2–restricted, CEA-specific antitumor CTL responses. This finding is supported by three lines of evidence: (a) an effective HLA-A2–restricted, CEA₆₉₁-specific CTL response; (b) specific in vitro killing of CEA-A2Kb transduced MC-38 colon carcinoma cells; and (c) protective immunity induced in vaccinated mice against challenges of these tumor cells. Importantly, peripheral T cell tolerance against CEA in CEA-A2Kb double transgenic mice was broken by the CEA₆₉₁ (IMIGVLGV) minigene vaccine. In conclusion, CEA-A2Kb double transgenic mice were demonstrated to be good candidates for in vivo testing of human CEA–based vaccines. This result suggests a potential for these vaccines in future human vaccine development. The feasibility of using nonmutated self-antigens as targets for therapeutic vaccinations was indicated, provided that such antigens are presented in an immunogenic context; that is, as a DNA minigene in a bacterial carrier system.

A lack of relevant animal models has hampered preclinical screening and critical evaluation of the efficacy of human vaccines in vivo. Carcinoembryonic antigen–A2Kb (CEA–A2Kb) double transgenic mice provide a biologically relevant model for preclinical screening and critical evaluation of human CEA vaccine efficacy in vivo, particularly because such animals are peripherally tolerant of CEA. We established the utility of this model by demonstrating that an oral DNA minigene vaccine induces effective HLA–A2–restricted, CEA-specific antitumor CTL responses. This finding is supported by three lines of evidence: (a) an effective HLA–A2–restricted, CEA₆₉₁-specific CTL response; (b) specific in vitro killing of CEA–A2Kb transduced MC–38 colon carcinoma cells; and (c) protective immunity induced in vaccinated mice against challenges of these tumor cells. Importantly, peripheral T cell tolerance against CEA in CEA–A2Kb double transgenic mice was broken by the CEA₆₉₁ (IMIGVLGV) minigene vaccine. In conclusion, CEA–A2Kb double transgenic mice were demonstrated to be good candidates for in vivo testing of human CEA–based vaccines. This result suggests a potential for these vaccines in future human vaccine development. The feasibility of using nonmutated self-antigens as targets for therapeutic vaccinations was indicated, provided that such antigens are presented in an immunogenic context; that is, as a DNA minigene in a bacterial carrier system.

Introduction

CD8⁺ CTLs have the ability to specifically recognize and kill tumor cells. They recognize antigens (Ag's) in the form of short peptides, generally 8 to 10 amino acids long, presented on the cell surface by MHC class I molecules. These peptides, usually referred to as CTL epitopes, are generated in the cytosol of cells after proteolytic processing of antigens by the proteasome (1). The primary aim of tumor vaccines is to induce antitumor CD8⁺ CTL responses that can eradicate tumors and prevent their relapse. DNA vaccines provide an attractive approach to this goal, particularly because vaccines against tumor self-antigens, consisting of either killed tumor cells or recombinant proteins, proved to be inefficient for delivery of antigen into the MHC class I Ag–processing pathway (2). Consequently, the induction of a more effective antigen-specific immune response by DNA vaccines requires new strategies for optimization of the vaccine design, including novel approaches for vaccine delivery and effective antigen processing. Such strategies include the use of an oral carrier system with an attenuated strain of *Salmonella typhimurium* (*dam*[−]; *AroA*[−]), which delivers the DNA to secondary lymphoid organs (3, 4).

Nonstandard abbreviations used: antigen (Ag); carcinoembryonic antigen peptide 1 (CEA1); carcinoembryonic antigen (CEA); effector/target (E/T); magnetic-activated cell sorting (MACS).

Conflict of interest: R.A. Reisfeld is a consultant for EMD-Lexigen Research Center, Billerica, Massachusetts, and received partial funding for this research from this company as indicated in the Acknowledgments.

The use of minigene vaccines is an attractive approach because of the ease of synthesis and manipulation of these vaccines. Moreover, in contrast to whole-gene vaccines, minigene vaccines can induce immune responses against specific Ag epitopes while avoiding the interference of nonrelevant Ag epitopes. Consequently, such vaccines lend themselves to in-depth studies of immunological mechanisms far more readily than do DNA vaccines encoding entire genes. The minigene strategy was reported to induce effective antitumor responses by an HLA–A2–restricted Melan-A peptide analog epitope (5) or by murine MHC class I molecule H-2D^b/K^b–restricted melanoma Ag epitopes (4).

Carcinoembryonic antigen (CEA), an oncofetal protein with a relative molecular mass of 180,000, is considered to be an effective target for a DNA vaccine because it is overexpressed by most colorectal, gastric, and pancreatic carcinomas (6), by 50% of breast cancers, and by 70% of non-small cell lung carcinomas; it is expressed to a far lesser extent on normal epithelium and also on some fetal tissues (7). This increased expression of CEA also promotes an increase in intercellular adhesions that may contribute to metastasis (8). Circulating CEA can also be detected in the blood of most patients with CEA-positive tumors and has been used to monitor responses to therapy and disease progression. Because of the overexpression of CEA on a large number of epithelial tumor cells, a variety of whole CEA gene- or CEA peptide-based vaccines have been the research focus of several laboratories (9–12) and used in clinical trials (13, 14).

Moreover, short peptides corresponding to HLA–A2–restricted CTL epitopes derived from CEA have been identified and were

shown to contribute to the cytotoxicity against tumor cells *in vitro* (9, 15, 16). These observations prompted us to adopt a minigene approach to developing CEA-specific DNA vaccines designed for optimal antitumor activity and to avoid the induction of immune responses that are cross-reactive with normal cells.

To this end, two different HLA-A2-restricted epitopes were selected: carcinoembryonic antigen peptide 1-6D (CAP1-6D) (YLSGADLNL) and CEA₆₉₁ (IMIGVLVGV). CAP1-6D was selected because it is an agonist peptide for CAP-1 (9) and was shown to be more antigenic than CAP-1 (17). CEA₆₉₁ was chosen because it was reported to be presented by HLA-A2-expressing tumor cells (15).

Results

A CEA minigene encoded by expression vectors is expressed in mammalian cells. To achieve optimal vaccine efficacy, three expression vectors were constructed based on the backbone of pCMV/ER/Myc (Figure 1A). To check gene expression, 293T cells were transfected with either pHI-*myc*, pHI-CAP1-6D-*myc*, or pHI-691-*myc* using Lipofectamine 2000 (Invitrogen). Protein expression was assessed by Western blotting of cell lysates with monoclonal anti-*myc* Ab (Invitrogen), and single bands with the expected molecular weight of 15 kDa or 16 kDa were detected (Figure 1B). A lysate from cells transfected with pHI-CAP1-6D-*myc* revealed patterns identical to those of pHI-691-*myc* (data not shown). The vaccine vectors pHI, pHI-CAP1-6D, and pHI-691 were generated by introducing a stop codon immediately downstream from the peptide coding sequences, so that mature peptides did not contain the *myc* epitope. Structures were confirmed by DNA sequencing, and empty pCMV vectors were also included for control purposes.

CEA₆₉₁-specific, HLA-A2-restricted immunity is induced by a DNA vaccine encoding the pHI-691 CEA minigene. To verify that a specific immune response was induced by the minigene vaccines, vaccination vectors were transfected into doubly attenuated *S. typhimurium* (*dam*⁻; *AroA*⁻) by electroporation and used to vaccinate C57-CEA-A2Kb double transgenic mice three times at 2-week intervals. To this end, ELISPOT assays were performed 2 weeks after the last immunization with splenocytes isolated from immunized mice; synthetic peptides (10 µg/ml) were applied as stimulators. All experimental groups revealed an increased number of spots when splenocytes were stimulated with the CEA₆₉₁ peptide, compared with unstimulated splenocytes. Although this increase is minimal in the groups of mice immunized with either the pCMV, pHI, or pHI-CAP1-6D DNA vaccines, it is quite dramatic in the mice vaccinated with pHI-691 (Figure 2A), which suggests the existence of CEA₆₉₁-specific cells that can be induced to secrete IFN-γ in C57-CEA-A2Kb double transgenic mice.

However, in all experimental groups, stimulation of splenocytes with the CAP1-6D peptide failed to significantly increase the number of spots compared with unstimulated splenocytes; that is, CAP1-6D-specific, IFN-γ-secreting cells could not be detected. This finding suggests that CAP1 may not be a dominant Ag epitope in CEA-A2Kb double transgenic C57BL/6J mice, despite the fact that it is one of the more dominant HLA-A2-restricted, CEA-specific epitopes in humans (9, 17). This notion is further supported by the finding that no CAP1-6D-specific, IFN-γ-secreting cells were detected in mice immunized with a vector encoding the full-length CEA gene (data not shown).

To confirm that the CEA₆₉₁-specific immune response induced was indeed HLA-A2 restricted, splenocytes from vaccinated mice were also cultured *in vitro* in the presence of irradiated (1,000 Gy) MC-38-CEA-A2Kb cells for 5 days and thereafter used in ELISPOT

assays. HLA-A2⁺ human T2 cells deficient in transporter associated with antigen processing (TAP) were used as stimulators. Such cells were used either unloaded or loaded overnight with 10 µg/ml CAP1-6D or CEA₆₉₁ peptides and irradiated (1,000 Gy). In mice immunized with the pHI-691 DNA minigene vaccine, an increased number of IFN-γ-secreting cells was detected when splenocytes from such mice were stimulated with CEA₆₉₁-loaded T2 cells. This increase was particularly evident when compared with splenocytes that were stimulated with either unloaded or CAP1-loaded T2 cells (Figure 2B). Similar results were obtained by substituting T2 cells with another HLA-A2⁺ cell line, B3 (data not shown). B3 is an EBV-transformed human B cell line established in our laboratory from a normal individual, which maintained high levels of HLA-A2 expression (Figure 2C). Because HLA-A2 is the only MHC molecule in common among the stimulating T2 or B3 cells of human origin and the responding CEA-A2Kb transgenic mouse splenocytes, these data suggest that the CEA₆₉₁-specific reaction observed is indeed HLA-A2 restricted.

When compared with those with no stimulation added to the splenocytes, the addition of irradiated T2 cells by themselves induced more splenocytes to secrete IFN-γ in every experimental group tested. However, this finding is not surprising because of the human origin of T2 cells. This reaction was stronger in the pHI group than in the pCMV vaccine group of mice, which suggests that pHI is an effective immune stimulator. Moreover, stimulation with CEA₆₉₁-loaded T2 cells failed to induce more cells to secrete IFN-γ in the pCMV, pHI, and pHI-CAP1-6D experimental groups of mice. This failure may be

Figure 1 Expression vectors are constructed and verified. (A) Schematic map of vector constructs. Minigenes encoding HIVtat translocation peptide, a spacer, and human CEA epitopes CAP1-6D or CEA₆₉₁ were assembled by PCR with overlapping oligonucleotides as templates. The PCR fragments generated were cloned into a pCMV vector by using *Bss*HI and *Xho*I restriction sites. (B) Proteins encoded by minigenes were expressed in mammalian cells. This expression was indicated when 293T cells were transfected with either pHI-*myc* or pHI-691-*myc* for 24 hours, harvested, lysed, and analyzed by Western blotting with monoclonal antibody against *myc*.

Figure 2

An HLA-A2–restricted, CEA₆₉₁-specific response is induced by the pHI-691 DNA minigene vaccine. Groups of C57BL/6-CEA-A2Kb mice ($n = 4$) were immunized three times at 2-week intervals with attenuated *S. typhimurium* harboring the vectors indicated. Two weeks after the last immunization, mice were sacrificed and ELISPOT assays performed on splenocytes isolated by using synthetic peptides (10 μ g/ml) as stimulators (A). The remaining splenocytes were stimulated with irradiated MC-38-CEA-A2Kb cells for 5 days, and ELISPOT assays were then performed using either irradiated unloaded or peptide-loaded T2 cells as stimulators (B). (C) HLA-A2 expression of T2 (left) and B3 (right) cells. B3 is an EBV-transformed cell line generated from a healthy HLA-A2⁺ individual as described in Methods. Cells were treated with control antibody (thin dashed lines) or anti-HLA-A2 antibody (thick solid lines) and then stained with PE-conjugated goat anti-mouse Ig.

caused by the dominance of the responses induced against T2 cells, which are xenogenic, except for their HLA-A2 expression.

HLA-A2–restricted, CEA₆₉₁-specific responder cells are cytotoxic. The fact that the HLA-A2–restricted, CEA₆₉₁-specific responder cells are cytotoxic was confirmed with standard ⁵¹Cr-release assays performed with splenocytes isolated from immunized mice. Target cells included CAP1-6D–loaded or CEA₆₉₁-loaded T2 cells. CAP1-6D–loaded T2 cells were used as a control because CAP1-6D–specific cells could not be detected in ELISPOT assays. Splenocytes obtained from the pHI-691 experimental group of mice exhibited significantly higher killing of CEA₆₉₁-loaded T2 cells than did splenocytes from pCMV, pHI, and pHI-CAP1-6D control groups ($P < 0.0005$, $P < 0.0005$, and $P < 0.005$ at an effector/target [E/T] ratio of 100:1, respectively [Figure 3A]). However, when T2 cells loaded with CAP1-6D were used as targets, the cytotoxic activity of splenocytes isolated from the pHI-691–immunized group was less significant compared with that of mice vaccinated with either pHI or pHI-CAP1-6D ($P < 0.05$ and $P > 0.05$ at an E/T ratio of 100:1, respectively [Figure 3B]), which indicates the specificity of this cytotoxic activity. As previously mentioned, because both effector

Figure 3

HLA-A2–restricted, CEA₆₉₁-specific T cells induced by the pHI-691 minigene vaccine are cytotoxic. Groups of C57BL/6-CEA-A2Kb mice ($n = 4$) were immunized three times at 2-week intervals with attenuated *S. typhimurium* harboring the vectors indicated. Mice were sacrificed 2 weeks after the last immunization, and isolated splenocytes were stimulated with irradiated MC-38-CEA-A2Kb cells for 5 days. Cytotoxicity assays were performed with (A) CEA₆₉₁-loaded T2 cells or (B) CAP1-6D–loaded T2 cells as targets.

mouse splenocytes and human T2 target cells only share HLA-A2, this specific cytotoxicity might be HLA-A2 restricted as well.

CD8⁺ T cells mediate HLA-A2–restricted cytotoxic killing. To verify that the induced HLA-A2–restricted, CEA₆₉₁-specific killing was mediated by CD8⁺ T cells, freshly isolated splenocytes were fractionated into CD8⁺ and CD8⁻ subpopulations by magnetic-activated cell sorting (MACS). The purity of the cell fractions is shown in Figure 4A. These fractionated cells were stimulated with irradiated MC-38-CEA-A2Kb in the presence of IL-2 for 5 days, and then standard ⁵¹Cr-release assays were performed using CEA₆₉₁-loaded T2 cells as targets. Killing of target cells was only observed with the CD8⁺ population, whereas the CD8⁻ population showed hardly any killing at all (Figure 4B). The CD8⁺ population from the pHI-691 experimental group of mice showed higher cytotoxicity than that of the pHI-CAP1-6D group, which was used as a control group in this experiment ($P < 0.005$, $P < 0.005$, and $P < 0.05$ at E/T ratios of 20:1, 10:1, and 5:1, respectively [Figure 4C]).

When CD8⁺ cells were enriched by MACS, the percentage of CD8⁺ T cells increased from approximately 30% in the unfractionated culture to more than 90% in the CD8⁺ cell culture. However, the CD8⁺ fraction did not show higher killing rates (Figure 4C) when compared with unfractionated splenocytes (Figure 3A), presumably because of the requirement of CD8⁺ T cells for optimal proliferation in cell culture. One line of evidence supporting this notion is that culture of the CD8⁺ fraction resulted in lower CD8 expression when compared with the unfractionated cultured splenocytes (data not shown).

**Figure 4**

DNA minigene-induced cytotoxicity is mediated by CD8⁺ T cells. Groups of C57BL/6-CEA-A2Kb mice ($n = 4$) were immunized three times at 2-week intervals with attenuated *S. typhimurium* harboring either pHI-CAP1-6D or pHI-691 vectors. Mice were sacrificed 2 weeks after the last immunization, and isolated splenocytes were fractionated into CD8⁺ or CD8⁻ populations. Each cell population was stimulated with irradiated MC-38-CEA-A2Kb cells for 5 days. Thereafter, cytotoxicity assays were performed with CEA₆₉₁-loaded T2 cells as targets. (A) Purity of each subpopulation after MACS. (B) Cytotoxicity of each cell population at E/T ratio of 20:1. (C) Cytotoxicity of CD8⁺ populations is shown at different E/T ratios.

Taken together, these data indicate that the pHI-CEA₆₉₁ minigene vaccine can effectively induce an HLA-A2-restricted, CEA₆₉₁-specific CTL response in CEA-A2Kb double transgenic mice.

Protective immunity against CEA-A2Kb-transduced colon carcinoma cells. HLA-A2-restricted, CEA₆₉₁-specific CTLs, induced by the pHI-691 minigene DNA vaccine, recognized and killed CEA-A2Kb doubly transduced MC-38 murine colon carcinoma cells, that is, MC-38-CEA-A2Kb cells, whose surface expression of HLA-A2 and CEA is depicted in Figure 5A (left). This process was demonstrated by isolating splenocytes from mice 2 weeks after the last immunization and stimulating them in vitro with irradiated MC-38-CEA-A2Kb cells for 5 days and then testing them in a standard ⁵¹Cr-release assays. As expected, splenocytes from the group of mice immunized with the pHI-691 vaccine showed the most effective cytotoxic killing of MC-38-CEA-A2Kb target cells when compared with pCMV, pHI, and pHI-CAP1-6D control groups ($P < 0.0005$, $P < 0.001$, and $P < 0.005$ at an E/T ratio of 100:1, respectively [Figure 5B]). This enhanced killing ability appeared to be HLA-A2 restricted because the killing percentage of the HLA-A2⁻ MC-38-CEA cells (HLA-A2

and CEA expression shown in Figure 5A [right]) or parental MC-38 target cells did not differ significantly among the experimental groups ($P > 0.05$ at an E/T ratio of 100:1 [Figure 5C and data not shown]). Taken together, these data suggest that those immune cells that presumably are HLA-A2 restricted and CEA₆₉₁-specific CTLs, induced by the pHI-691 vaccine, are indeed capable of recognizing and killing CEA-A2Kb doubly transfected MC-38 cells in vitro.

To test the specificity of this immune response, splenocytes isolated from pHI-691 vaccinated group of mice were stimulated weekly with irradiated MC-38-CEA-A2Kb cells. These cells, after being restimulated four times, were more than 86% CD8⁺ as demonstrated by flow cytometry (Figure 6A). These stimulated cells were then harvested and analyzed by ⁵¹Cr-release assays against either unloaded or peptide-loaded HLA-A2* B3 cells. In ⁵¹Cr-release assays, the cytotoxic killing efficacy of CEA₆₉₁-loaded B3 cells was greatly enhanced; that is, a much higher killing percentage was observed at lower E/T ratios, with the specificity still being maintained as indicated by the lower percentage of specific killing of unloaded B3 cells (Figure 6B).

The presence of T cells able to kill tumor cells in the circulation of vaccinated animals suggests that this T cell response may also be effective in vivo, that is, protecting mice from a tumor challenge. To test this hypothesis, mice were challenged subcutaneously in the right flank with 5×10^5 MC-38-CEA-A2Kb cells 2 weeks after the last immunization. These animals were sacrificed 28 days later, and tumor weights were assessed. In all groups of experimental animals, tumor size varied considerably within each group. This

Figure 5

The DNA minigene vaccine pHI-691 induces HLA-A2-restricted killing of MC-38-CEA-A2Kb cells. (A) Surface expression of HLA-A2 and CEA by MC-38-CEA-A2Kb (left) and MC-38-CEA (right). Tumor cells were washed and incubated with isotype control Ab (thin dashed lines), anti-HLA-A2 (thin solid lines), or anti-CEA (heavy solid lines) and stained with PE-conjugated (Fab')₂ of goat anti-mouse Ig Ab. Groups of C57BL/6-CEA-A2Kb mice ($n = 4$) were immunized three times at 2-week intervals with attenuated *S. typhimurium* harboring the vectors indicated. Mice were sacrificed 2 weeks after the last immunization, and isolated splenocytes were stimulated with irradiated MC-38-CEA-A2Kb cells for 5 days. Thereafter, cytotoxicity assays were performed with (B) MC-38-CEA-A2Kb or (C) MC-38-CEA as target cells. max, maximum.

Figure 6

Repetitive stimulation with MC-38-CEA-A2Kb cells results in enriched HLA-A2–restricted, CEA₆₉₁-specific CTLs. C57BL/6-CEA-A2Kb mice ($n = 4$) were immunized three times at 2-week intervals with attenuated *S. typhimurium* harboring the pHI-691 vector. Mice were sacrificed 2 weeks after the last immunization, and isolated splenocytes were stimulated weekly with irradiated MC-38-CEA-A2Kb cells. After four stimulations, cells were harvested and cytotoxicity assays performed. (A) Expression of CD8 on stimulated cells. Stimulated splenocytes were stained with PE-conjugated isotype control antibody (thin dashed line) or anti-CD8 Ab (thick solid line). (B) Cytotoxicity assays performed with either unloaded or CEA₆₉₁-loaded B3 cells as targets.

finding is not too surprising because of the complex genetic background of the doubly transgenic mice and tumor cell lines. However, the average tumor size was still reduced in the pHI-691 group, and the difference reached significance when compared with the pCMV group ($P < 0.02$ [Figure 7A]). Importantly, 3 of 10 mice rejected the tumor challenge completely, whereas all mice in the pCMV, pHI, and pHI-CAP1-6D experimental groups uniformly developed tumors (Figure 7A). This experiment was repeated with similar results (data not shown). The protection by the minigene vaccine is specific for MC-38-CEA-A2Kb tumor cells as well as HLA-A2 restricted because no protection was observed against parental MC-38-CEA and MC-38 tumor cells (Figure 7B).

Discussion

The availability of CEA transgenic mice expressing CEA as a self-antigen with a tissue distribution similar to that of humans (18–20) provides a particularly relevant model for critically evaluating the potential efficacy of a human CEA–based vaccine because these animals developed peripheral tolerance to CEA. This finding is particularly evident from the lack of detectable, CEA-specific serum antibodies and the inability to prime an *in vitro* splenic T cell response to CEA. These transgenic mice already proved valuable for thorough evaluation of DNA vaccines encoding the entire CEA gene or for CEA-peptide vaccines *per se* (10, 21, 22). However, because human MHC class I alleles are distinct from those of mice, animals transgenic for only CEA were inadequate for testing HLA-A2–restricted minigene

vaccines, and HLA-A2Kb transgenic mice were required. Such mice express α_1 and α_2 domains of the human HLA-A2.1 molecule, as well as the α_3 domain from the mouse H-2K^b molecule (23). Indeed, mice transgenic for HLA-A2 were shown to be useful for studying human antigens *per se* and the immune response directed against them (12, 23–25). However, mice transgenic only for HLA-A2 are unsuitable for *in vivo* studies of HLA-A2–restricted, CEA-specific responses because such animals still recognize CEA as a foreign antigen and lack peripheral T cell tolerance against CEA. Consequently, for the studies reported here, CEA-A2Kb double transgenic mice were generated by breeding transgenic mice homozygous for CEA and HLA-A2Kb. Because such animals express human CEA antigen presented by human HLA-A2 molecules, they represent a most relevant *in vivo* animal model to study human immune responses to DNA-based CEA minigene vaccines and can be used for *in vivo* preclinical evaluations of the vaccines for specificity and therapeutic efficacy. Importantly, as predicted, the CEA-A2Kb–transduced colon carcinoma cell line MC-38 is tumorigenic in these CEA-A2Kb double transgenic mice; thus, it was possible to test the effectiveness of the applied vaccination *in vivo*. To our knowledge, our study is the first to utilize CEA-A2Kb double transgenic mice for such *in vivo* studies.

Figure 7

DNA minigene vaccine pHI-691 exhibits HLA-A2–restricted antitumor effects in CEA-A2Kb double transgenic mice. Groups of mice ($n = 7–10$) were immunized three times at 2-week intervals with attenuated *S. typhimurium* harboring the vectors indicated. Mice were challenged 2 weeks after the last immunization subcutaneously with 5×10^5 MC-38-CEA-A2Kb, MC-38, or MC-38-CEA cells. Mice were sacrificed 28 days later and tumor weights assessed. (A) MC-38-CEA-A2Kb tumor weight, the horizontal bar showed the average. (B) Average tumor weight of each group of mice ($n = 8$) challenged with different tumor cells. Top shows MC-38 tumor size; bottom shows average MC-38-CEA tumor weight. * $P < 0.02$ compared with pCMV group.

We tested two different HLA-A2–restricted CEA epitopes with our DNA minigene vaccines: CAP1-6D (YLSGADLNL) (9, 17) and CEA₆₉₁ (IMIGVLGV) (15). The DNA minigene vaccine pHI-691 clearly induced a relevant HLA-A2–restricted, CEA₆₉₁-specific CTL response similar to the response to this same CEA-peptide reported in humans (15). The biological relevance of this animal model was confirmed, because in CEA-A2Kb double transgenic mice, these CTLs specifically killed CEA-A2Kb–transduced MC-38 cells in vitro and protected mice from a challenge of these tumor cells in vivo.

It should be noted that the CEA-A2Kb transgenic mice still harbor a murine T cell receptor repertoire. In this regard, Theobald et al. (26) have demonstrated that a correlation between an immune response to some Ag epitopes observed in HLA-A2 transgenic mice and in vitro immune responses in humans does not necessarily exist. Consequently, whether this phenomenon is responsible for the failure of the pHI-CAP1-6D DNA minigene vaccine to induce a CAP1-6D–specific CTL response or whether the pHI-CAP1-6D DNA minigene vaccine itself is insufficient to induce such response deserves further investigation.

The rationale for using the HIVtat peptide, which is derived from the HIVtat Ag, in our minigene vaccine is based on the fact that it is one of the commonly used membrane-translocating peptides. These peptides are able to transport other peptides into the endoplasmic reticulum (ER) in a TAP-independent manner, where they can be processed and trimmed to CTL epitopes (27–29). Such peptides can be internalized in a receptor-independent and energy-independent fashion; however the exact mechanism by which they can translocate across the plasma membrane into the cytoplasm remains unknown (29). In our vaccine, CEA₆₉₁ was cloned downstream from the HIVtat peptide to ensure its proper delivery and processing in the proteasome. In this regard, Lu et al. (29) demonstrated that by linking to the HIVtat peptide, Ag epitope peptide can be transported into the cell to form complexes with MHC class I molecules in the ER and the *trans*-Golgi region. In addition, an orally delivered DNA minigene vaccine against murine melanoma (i.e., a plasmid encoding only peptides) was shown to be ineffective in inducing an epitope-specific response (4). When attenuated *S. typhimurium*, harboring vector encoding solely the CEA₆₉₁ peptide, were used to immunize mice, they induced a CEA₆₉₁-specific response detected by ELISPOT assays; however, this immune response was not as effective as that obtained with the pHI-691 vaccine (data not shown).

In summary, our data demonstrate that peripheral T cell tolerance against the CEA self-antigen could be broken by our pHI-691 DNA minigene vaccine in CEA-A2Kb double transgenic mice. This ability is indicated by an effective HLA-A2–restricted, CEA₆₉₁-specific CTL response, which can specifically kill CEA-A2Kb transduced MC-38 colon carcinoma cells in vitro and protect mice from a challenge by these tumor cells in vivo. This DNA minigene vaccine, thus, provides an interesting alternative design of CEA-based DNA vaccines for potential clinical use.

Methods

Animals, bacterial stains, and cell lines. C57BL/6J-CEA and C57BL/6J-A2Kb homozygous transgenic breeder mice were generated as previously described (18, 30). C57BL/6J-CEA-A2Kb double transgenic mice were generated in the animal facility of The Scripps Research Institute by crossing male C57BL/6J-CEA with female C57BL/6J-A2Kb mice. The genotype of such mice was confirmed by PCR and flow cytometry, respectively. All animal experiments were performed according to the NIH Guides for the Care and Use of Laboratory Animals.

The doubly attenuated *S. typhimurium* AroA⁻ and *dam*⁻ strain RE88 was kindly provided by Remedyne Corporation (Santa Barbara, California, USA). The murine colon carcinoma cell line MC-38-CEA was obtained as described before (18). MC-38-CEA-A2Kb cells were generated by transfecting MC-38-CEA cells with a plasmid encoding A2Kb. All cell lines were cultured in DMEM (Gibco; Invitrogen Corp., Grand Island, New York, USA) supplemented with 10% (vol/vol) FBS. MC-38-CEA cells were cultured in the presence of 1 mg/ml G418 (Sigma-Aldrich, St. Louis, Missouri, USA), and MC-38-CEA-A2Kb cells were cultured with G418 and 0.5 mg/ml Zeocin (Invitrogen, Carlsbad, California, USA). T2, a human HLA-A2⁺ cell line, was originally obtained from P. Cresswell (Yale University, New Haven, Connecticut, USA) and kindly provided by L.A. Sherman (The Scripps Research Institute). Another HLA-A2⁺ cell line, B3, was established by transforming PBMCs from a healthy HLA-A2⁺ individual with EBV.

Construction of expression vectors. The expression vector pCMV/ER/Myc was purchased from Invitrogen. Vector construction is illustrated schematically in Figure 1A. The following expression vectors were constructed: pHI-*myc*, pHI-CAP1-6D-*myc*, and pHI-691-*myc*, where HIVtat peptide represents RKKRRQRRR, CAP1-6D peptide represents YLSGADLNL (17), and CEA₆₉₁ peptide represents IMIGVLGV (15). All peptides were engineered to be in-frame with the *myc* epitope. Constructs were confirmed by DNA sequencing at The Scripps Research Institute's Core Facility (La Jolla, California, USA). Peptide expression was demonstrated by Western blotting with monoclonal anti-*myc* antibody (Invitrogen). Once peptide expression was verified, a stop codon was introduced immediately in front of the *myc* epitope sequences. The resulting vectors, namely pHI, pHI-CAP1-6D, and pHI-691, were verified by sequencing and used to transform doubly attenuated *S. typhimurium* (*dam*⁻; AroA⁻) for immunization. The pCMV empty vector was also included in the experiments as a control.

Transformation of *S. typhimurium*. Doubly attenuated *S. typhimurium* (*dam*⁻; AroA⁻) were transformed with DNA vaccine plasmids by electroporation. Briefly, freshly prepared bacteria (1 × 10⁸), at mid-log growth phase, were mixed with plasmid DNA (1 to 2 μg) on ice in a 0.1-cm cuvette and electroporated at 2.0 kV, 25 μF, and 100 Ω.

Peptide synthesis. The CAP1-6D peptide, with greater than 95% purity by HPLC, was a gift from J. Schlom (National Cancer Institute, Bethesda, Maryland, USA). The CEA₆₉₁ peptide was synthesized by Multiple Peptide System (San Diego, California, USA) with greater than 93% purity by HPLC.

Oral immunization and tumor cell challenge. Groups of C57BL/6J-CEA-A2Kb mice (*n* = 7–10) were immunized three times at 2-week intervals by gavage with 100 μl PBS that contained approximately 5 × 10⁸ doubly mutated *S. typhimurium* harboring either pCMV, pHI, pHI-CAP1-6D, or pHI-691. Mice were challenged subcutaneously in the right flank with 5 × 10⁵ MC-38-CEA-A2Kb colon carcinoma cells 2 weeks after the last immunization. The subcutaneous tumors were monitored daily. Mice were sacrificed 28 days after tumor challenge, and tumor weights were determined and compared with those of control subjects.

Cytotoxicity assay. Cytotoxicity was measured by a standard chromium-51 (⁵¹Cr) release assay as previously described, with some modification (31). Briefly, splenocytes were harvested 2 weeks after the last immunization and stimulated in vitro by irradiated (1,000 Gy) MC-38-CEA-A2Kb cells at 37°C for 5 days in RPMI 1640 supplemented with 10% FBS, L-glutamine, 15 mM HEPES, nonessential amino acids, sodium pyruvate, 2-ME, and recombinant IL-2 at 20 U/ml (PeproTech, Rocky Hill, New Jersey, USA). Splenocytes

were harvested and separated with Lympholyte-M cell separation media (Cedarlane Laboratories Ltd., Hornby, Ontario, Canada). Target cells were labeled with ⁵¹Cr for 1.5 hours at room temperature and incubated with effector cells at various effector-to-target cell ratios at 37°C for 4 hours. The percentage of specific target cell lysis was calculated with the formula [(E-S)/(T-S)] × 100, where E is the average experimental release, S is the average spontaneous release, and T is the average total release.

ELISPOT assays. ELISPOT assays were performed with an ELISPOT kit (BD Biosciences Pharmingen, La Jolla, California, USA) according to the instructions provided by the manufacturer. Briefly, splenocytes were isolated 2 weeks after the last immunization. After lysis of the red blood cells with ACK lysis buffer (Cambrex Bio Science, Walkersville, Maryland, USA), splenocytes were resuspended at a final concentration of 2 × 10⁷, and 100 μl of this suspension was then incubated with 100 μl medium with or without the peptides or irradiated stimulator cells overnight at 37°C in ELISPOT plates coated with anti-IFN-γ. In some cases, splenocytes were stimulated with irradiated (1,000 Gy) MC-38-CEA-A2Kb cells for 5 days, and ELISPOT assays were performed thereafter.

MACS and flow cytometry. MACS was performed with anti-mouse CD8 Ab conjugated magnetic beads (Miltenyi Biotec, Sunnyvale, California, USA) according to the manufacturer's instructions. The purity of fractionated cell populations was checked by flow cytometry using phycoerythrin-conjugated (PE-conjugated) anti-mouse CD8 Ab. Flow cytometry was performed with 1 × 10⁶ cells on a FACSCalibur (Becton Dickinson, San Jose, California, USA) equipped with a CellQuest program. Analyses were performed with FlowJo software (Tree Star Inc., Ashland, Oregon, USA). Other

antibodies used in such analyses included purified anti-HLA-A2 Ab (BD Biosciences Pharmingen), purified anti-CEA Ab (ICN Biomedicals Inc., Aurora, Ohio, USA), and PE-conjugated F(ab')₂ of goat anti-mouse Ig Ab (Southern Biotechnology Associates Inc., Birmingham, Alabama, USA).

Statistical analysis. The statistical significance of differential findings between experimental groups and control groups was determined by Student's *t* test. Findings were regarded as significant if two-tailed *P* values were less than 0.05.

Acknowledgments

We thank Gaston Picchio, C. Dolman, and D. Markowitz for excellent technical assistance and Kathy Cairns for editorial assistance with manuscript preparation. H. Zhou is currently a fellow of The Susan G. Komen Breast Cancer Foundation. This study was supported by NIH grant CA83856 (to R.A. Reisfeld), Department of Defense grants DAMD17-02-10562 and DAMD17-02-1-0137 (to R. Xiang), and E. Merck, Darmstadt-Lexigen Research Center (Billerica, Massachusetts, USA) grant SFP1330 (to R.A. Reisfeld). Scripps Research Institute manuscript number: 16339-IMM.
