FK506 activates BMPR2, rescues endothelial dysfunction, and reverses pulmonary hypertension

Edda Spiekerkoetter, … , Peter ten Dijke, Marlene Rabinovitch

Dysfunctional bone morphogenetic protein receptor-2 (BMPR2) signaling is implicated in the pathogenesis of pulmonary arterial hypertension (PAH). We used a transcriptional high-throughput luciferase reporter assay to screen 3,756 FDA-approved drugs and bioactive compounds for induction of BMPR2 signaling. The best response was achieved with FK506 (tacrolimus), via a dual mechanism of action as a calcineurin inhibitor that also binds FK-binding protein-12 (FKBP12), a repressor of BMP signaling. FK506 released FKBP12 from type I receptors activin receptor-like kinase 1 (ALK1), ALK2, and ALK3 and activated downstream SMAD1/5 and MAPK signaling and ID1 gene regulation in a manner superior to the calcineurin inhibitor cyclosporine and the FKBP12 ligand rapamycin. In pulmonary artery endothelial cells (ECs) from patients with idiopathic PAH, low-dose FK506 reversed dysfunctional BMPR2 signaling. In mice with conditional Bmpr2 deletion in ECs, low-dose FK506 prevented exaggerated chronic hypoxic PAH associated with induction of EC targets of BMP signaling, such as apelin. Low-dose FK506 also reversed severe PAH in rats with medial hypertrophy following monocrotaline and in rats with neointima formation following VEGF receptor blockade and chronic hypoxia. Our studies indicate that low-dose FK506 could be useful in the treatment of PAH.

Introduction
Idiopathic pulmonary arterial hypertension (IPAH) is a rare disorder thought to develop following a genetic and/or environmental insult that triggers endothelial cell (EC) apoptosis, loss of distal vessels, and occlusive vascular remodeling (1). These pathological changes increase resistance to pulmonary flow and cause progressive right heart failure. Current therapies mainly include drugs with vasodilator activity (2) and pulmonary artery balloon angioplasty (3), leaving heart-lung transplantation as the only option for many patients. Therefore, new approaches are needed that focus on activating cellular mechanisms to reverse vascular remodeling. One strategy could be to improve function of the bone morphogenetic protein receptor-2 (BMPR2) pathway. Germline mutations causing loss of BMPR2 function are found in >80% of familial and approximately 20% of sporadic cases of IPAH (4, 5). Acquired somatic chromosomal abnormalities in the BMPR2 signaling pathway have also been described (6). The low penetrance of pulmonary arterial hypertension (PAH) found in nonaffected family members with a BMPR2 mutation has been attributed to a higher level of BMPR2 expression from the normal allele (7). In addition, patients with IPAH without a BMPR2 mutation or with PAH associated with other conditions have reduced expression of BMPR2 in pulmonary arteries (8). Furthermore, estrogen can reduce BMPR2 expression, perhaps explaining the propensity of females to develop PAH (9). IL-6, a cytokine increased in the blood of patients with IPAH, can reduce BMPR2 expression via a STAT3-miR17/92–mediated mechanism (10). Furthermore, patients with a BMPR2 mutation have worse pulmonary vascular remodeling (3). The importance of BMPR2 dysfunction in PAH is supported by studies in transgenic mice. Mice with deletion of BMPR2 in ECs (11) develop PAH, as do mice expressing a dominant-negative Bmpr2 gene after birth in vascular SMCs (12). Mice heterozygous for Bmpr2 develop exaggerated PAH in response to hypoxia and serotonin (13). Reduced BMPR2 expression also occurs in monocrotaline (14) and chronic hypoxic (15) rat models of PAH, and delivery of BMPR2 by intravenous gene therapy attenuates the disease in both models (16, 17). Moreover reconstitution of athymic rats with regulatory T cells also prevents PAH resulting from blockade of the VEGF receptor, coincident with an increase in BMPR2 expression in ECs (18). Since clinical application of BMPR2 gene therapy poses challenges, we sought to identify an FDA-approved drug with a known pharmacokinetic and toxicity profile that increases signaling through the BMPR2 pathway. We applied a high-throughput assay to screen available libraries, and agents that appeared to activate the receptor were further tested in human pulmonary arterial

Dysfunctional bone morphogenetic protein receptor-2 (BMPR2) signaling is implicated in the pathogenesis of pulmonary arterial hypertension (PAH). We used a transcriptional high-throughput luciferase reporter assay to screen 3,756 FDA-approved drugs and bioactive compounds for induction of BMPR2 signaling. The best response was achieved with FK506 (tacrolimus), via a dual mechanism of action as a calcineurin inhibitor that also binds FK-binding protein-12 (FKBP12), a repressor of BMP signaling. FK506 released FKBP12 from type I receptors activating receptor-like kinase 1 (ALK1), ALK2, and ALK3 and activated downstream SMAD1/5 and MAPK signaling and ID1 gene regulation in a manner superior to the calcineurin inhibitor cyclosporine and the FKBP12 ligand rapamycin. In pulmonary artery endothelial cells (ECs) from patients with idiopathic PAH, low-dose FK506 reversed dysfunctional BMPR2 signaling. In mice with conditional Bmpr2 deletion in ECs, low-dose FK506 prevented exaggerated chronic hypoxic PAH associated with induction of EC targets of BMP signaling, such as apelin. Low-dose FK506 also reversed severe PAH in rats with medial hypertrophy following monocrotaline and in rats with neointima formation following VEGF receptor blockade and chronic hypoxia. Our studies indicate that low-dose FK506 could be useful in the treatment of PAH.
Figure 1
High-dose FK506, the main activator of BMP signaling found in the high-throughput screen, recapitulates BMP4 signaling and function. (A) BRE-luciferase activity in different numbers of C2C12 cells at different concentrations of BMP4. BMP4 at the EC-20 concentration of 250 pM for 1,500 cells per 60 μl per well permitted identification of coactivators. (B) Percentage BRE-luc activation, compared with 250 pM BMP4, in 6-point serial dilution for FK506 and rapamycin. (C) BRE-luciferase activity in C2C12 cells comparing FK506 (FK; 2 μg/ml), rapamycin (Rapa; 4 μg/ml), cyclosporine (Cyclo; 2 μg/ml), and Shield-1 (1 μg/ml) (n = 8; ***P < 0.001 vs. CON, +++P < 0.001 vs. FK506, 1-way ANOVA, Bonferroni multiple-comparison test). (D) In human PAECs, ID1 expression relative to B2M mRNA 24 hours after stimulation with vehicle (CON), FK506 (15 ng/ml), or rapamycin (10 ng/ml) (n = 3; **P < 0.01 vs. vehicle, 1-way ANOVA, Dunnett's post test). (E and F) Representative Western immunoblot and relative densitometric analysis of PAECs showing (E) pSMAD1/5/8 and (F) ID1 relative to β-actin following stimulation with BMP4 (10 ng/ml) or FK506 (15 ng/ml) (n = 3; *P < 0.05, **P < 0.01 vs. CON, 2-way ANOVA). (G) Assessment of apoptosis with measurement of caspase-3/7 luminescence 24 hours after serum starvation and treatment with BMP4 (10 ng/ml) or FK506 (15 ng/ml). (n = 5; *P < 0.05; **P < 0.01 vs. CON, 1-way ANOVA, Dunnett's post test). (H) Representative images from a Matrigel tube formation assay. Tube number and length were assessed after 8 hours in unstimulated cells (CON) or following stimulation with VEGF (20 ng/ml), BMP4 (10 ng/ml), or FK506 (15 ng/ml). (n = 6; *P < 0.05; **P < 0.01 vs. CON, 1-way ANOVA, Dunnett's post test). Scale bar: 100 μm. Mean ± SEM.
ECs (PAECs), including those from patients with dysfunctional BMPR2 signaling. The mechanism of BMPR2 activation by the most effective compound was investigated. Then the compound was tested in experimental PAH animal models for its efficacy in rescuing dysfunctional EC signaling and gene regulation and in preventing and reversing PAH.

**Results**

*High-throughput screen yields activators of BMPR2 signaling.* Like other members of the TGF-β family, BMPs elicit their effects through activation of receptor complexes, composed of a type II receptor (BMPR2, ActivinR2A, or ActivinR2B) and a type I receptor (ALK3 [also known as BMPR1A], ALK6 [also known as BMPR1B], ALK2, or ALK1). This results in activation of multiple signaling pathways, such as MAPK, PI3K (pAKT), and pSMAD, and downstream transcription factors, such as PPARY (19) and inhibitor of differentiation 1 (ID1) (20). The latter is a basic helix-loop-helix (HLH) transcription factor that binds other HLH transcription factors and acts as a dominant-negative antagonist (21). As substrates of the ubiquitin/26S proteasome system that regulate protein stability, ID proteins are short-lived, with a half-life of 30 minutes (22). As an early response gene (23), ID1 is transcribed in a pSMAD1/5-dependent manner (24) and thus is used commonly as a read out for BMPM2 signaling in vascular cells (20, 25, 26). Furthermore, ectopic ID1 expression induces EC migration and tube formation (26).

In developing the high-throughput assay to assess activation of BMPR2 signaling, we used the C2C12 mouse myoblastoma cell line stably transfected with a construct in which the BMP/MAPK elements of the ID1 promoter were linked to luciferase (BRE-luc). We optimized conditions to improve the luciferase signal related to varying the cell number, adding test compounds and the luciferase substrate. Plating 1,500 cells in 384-well plates without exogenous BMP4 (%) exogenous BMP4 (%)

Activators of ID1 expression without and with exogenous BMP4 ligand found in high-throughput screen of 3,756 FDA-approved drugs and bioactive compounds (20 μM each). 100% of activation is defined as BRE-luc activity relative to the EC-20 dose of 250 pM BMP4. Only activators that increase BRE-luc activity >10% are shown. CML, chronic myelogenous leukemia.
other pulmonary artery vascular cells (8), and PAEC dysfunction has been implicated in the pathogenesis of PAH (11, 19, 28). Rapamycin attenuates chronic hypoxic PAH (29), but its effect on monocrotaline-induced PAH in rats is not unequivocal (30, 31).

FK506 had not been previously tested in experimental PAH. We stimulated PAECs with 15 ng/ml FK506 or 10 ng/ml rapamycin, concentrations used to induce immunosuppression in the clinical setting. Consistent with the BMP/SMAD transcriptional luciferase assay, we confirmed a significant increase in ID1 mRNA 24 hours after stimulation with FK506, but only a trend was evident with rapamycin (Figure 1D). We then showed that FK506 was
Figure 3
Low-dose FK506 rescues IPAH mvPAEC dysfunction. (A) Representative immunoblot and densitometry showing BMPR2 and ID1/β-actin in human PAECs stimulated with BMP4 (10 ng/ml) or FK506 (15 ng/ml) following knockdown of BMPR2 with BMPR2si compared with NTsi as control (n = 3; *P < 0.05 vs. CON, 2-way ANOVA). (B) Representative immunoblot and densitometry of mvPAECs from 3 patients with IPAH showing ID1/β-actin at baseline (CON) or at various time points after stimulation with BMP4 (10 ng/ml) or FK506 (15 ng/ml) (n = 3; *P < 0.05 vs. CON, 2-way ANOVA). (C) ID1/18S mRNA 4 hours after and apelin/18S mRNA 8 hours after stimulation with BMP4 (10 ng/ml) and low-dose FK506 (0.2 ng/ml) in the same IPAH mvPAECs as in B (n = 3; *P < 0.05; **P < 0.01, vs. CON, 1-way ANOVA, Dunnett’s post test). (D) Representative images and quantitative analysis of tube number and length of tubes formed in Matrigel with mvPAECs from a patient with IPAH 4 hours after unstimulated CON, VEGF (10 ng/ml), BMP4 (10 ng/ml), and FK506 (0.2 ng/ml) (n = 6; ***P < 0.001; **P < 0.01 vs. CON, 1-way ANOVA, Dunnett’s post test; scale bar: 100 μm). (E) Proposed model of activation of BMPR2 in the presence of a subactivating dose of BMPs and an activating dose of BMPs and mutated or dysfunctional BMPR2 receptor with an activating dose of BMPs or with a subactivating dose of BMPs and FK506. Mean ± SEM.
similar to BMP4 in promoting PAEC survival following serum withdrawal, as judged by the Caspase-Glo 3/7 apoptosis assay (Figure 1G). In addition, BMP4 and FK506 were comparable to VEGF (20 ng/ml) in inducing formation of PAEC tubular networks in Matrigel (Figure 1H).

FK506 binds to and removes FKBP12 from BMP type I receptors. Previous data suggested that a low subimmunosuppressive dose of FK506 can prevent neointima formation in a carotid artery injury model in Apoe−/− mice (33, 34). We confirmed in microvessel PAECs (mvPAECs) that FK506, in concentrations as low as 0.2 ng/ml, increased Id1 mRNA and protein (Figure 2, A and B, respectively). The mechanism of action of FK506 was then investigated. Previous studies have shown that a BMP ligand (BMP2, BMP4, BMP6, BMP7, and BMP9) can initiate the interaction of a type II receptor with serine/threonine kinase activity (BMPR2, ActivinR2A, or ActivinR2B) with a type I receptor (ALK1, ALK2, ALK3, and ALK6), resulting in its phosphorylation (35). We therefore determined whether FK506 requires the kinase activity to induce BMP signaling. When we pretreated C2C12 BRE-luc cells with a BMP type I receptor kinase inhibitor, LDN-193189, FK506 failed to induce BMP signaling, as judged by BRE-luciferase (ID1 expression) (Figure 2C) as well as pSMAD1/5 (Supplemental Figure 2A). These features were replicated by LDN-193189 inhibition of BMP6 activation of BMP signaling (BRE-luciferase) as a positive control. When BMPR2 was reduced by siRNA (documented in Supplemental Figure 2B), there was only a partial decrease in ID1 expression (Figure 2D), suggesting that another type II receptor such as Activin R2A could substitute. In fact, we were able to show that reducing both ActivinR2A and BMPR2 by siRNA caused an additive decrease in ID1 expression (Figure 2D), consistent with previous reports (36).

FKBP12 interacts with TGF-β type I family receptors and blocks signaling by occupying the phosphorylation site at its glycine-serine–rich region (37). We hypothesized that FK506-mediated BMP signaling was related to its interaction with and removal of FKBP12 (38) from type I receptors involved in BMP signaling, in addition to its known function as an inhibitor of the phosphatase calcineurin (39). By coimmunoprecipitation of 293T cell lysates transfected with plasmids containing FLAG-tagged FKBP12 as well as HA-tagged ALK1, ALK2, or ALK3, we showed that FKBP12 binds to type I receptors involved in BMP signaling and that FK506 releases FKBP12 from all 3 tested (Figure 2E). We then assessed which of the type I receptors was predominantly involved in FK506-mediated BMP signaling. We knocked down ALK1, ALK2, and ALK3 by siRNA in BRE-luc cells and assessed whether the loss of any one of the above receptors would compromise BMP4- or FK506-induced BRE luciferase activity. While BMP4 predominantly signaled via ALK3 and, to a lesser extent, ALK1 (Figure 2F), FK506 was able to interact with all 3 receptors (Figure 2G). Rapamycin exclusively recruited ALK2 (Figure 2H), a receptor that is not involved in BMP4-induced BMP signaling and therefore does not appear to preferentially interact with BMPR2. We confirmed that cyclosporine did not interact with type I receptors (Supplemental Figure 2C).

FK506 binds and removes FKBP12 from multiple type I receptors that interact with BMPR2 or ActivinR2A, whereas rapamycin only engages FKBP12 bound to ALK2. This explains, perhaps, why BRE-luc activity is greater with FK506 than with rapamycin combined with the calcineurin inhibitor cyclosporine (Supplemental Figure 2D). We furthermore tested whether removing FKBP12 by siRNA would mimic FK506 function, allowing for an increase in ID1 expression. However, reducing levels of FKBP12 to 30% of control values (Supplemental Figure 2B) did not enhance BRE-luciferase (Supplemental Figure 2E). This suggests that incomplete depletion of FKBP12 is either not sufficient to activate type I BMP receptors (BRE-luc) or that engaging FKBP12 bound to the receptor and then removing it by FK506 may be required to activate the signaling machinery. We also assessed whether other FKBPbs could inhibit ligand-independent type I receptor activation. However, reducing levels of 6 other FKBPbs (FKBP12.6, FKBP13, FKBP25, FKBP54, and FKBP38) by siRNA, one at a time, did not induce BRE-luciferase activity (Supplemental Figure 2, F and G). These data are consistent with a redundancy in FKBPbs as binding partners of type I receptors. We confirmed FK506 activation of pSMAD1/5 as one read out for BMP signaling as well as others, such as pERK, pAKT, and p-c-JUN (Supplemental Figure 2, H–J).

FK506 rescues endothelial dysfunction in PAECs from patients with IPAH. To determine whether FK506 could rescue BMPR2 dysfunction in PAECs, we reduced BMPR2 protein levels to 50% of control values using RNAi (Figure 3A). As expected, these cells were unresponsive to BMP4 (10 ng/ml), but FK506 (15 ng/ml) increased ID1 in keeping with its ability to engage another type II receptor, specifically ActivinR2A (40). We then screened mvPAECs cultured from lungs harvested at transplant from 6 patients with IPAH that were obtained through the Pulmonary Hypertension Breakthrough Initiative Network. We found that mvPAECs from 3 out of the 6 patients did not increase pSMAD1/5 or ID1 in response to normally activating doses of BMP4 (10 ng/ml). One of these patients had a documented mutation in BMPR2 (c.961C>T; p.321R>R/X). In contrast, all mvPAEC cultures that did not respond to BMP4 showed an increase in pSMAD1/5 and ID1 1 hour after stimulation with FK506 (15 ng/ml) (Figure 3B). Interestingly, 4 hours after low-dose FK506 (0.2 ng/ml), ID1 mRNA was elevated, and at 8 hours, apelin mRNA was increased (Figure 3C). Apelin is regulated by BMPR2-mediated signaling (19) and is important in endothelial homeostasis. We further documented that FK506 (0.2 ng/ml) rescued dysfunction of IPAH PAECs by reversing their previously described impaired ability to form tubular networks in Matrigel (41). FK506 induced tube formation 4 hours after stimulation, in a manner comparable to that of VEGF (20 ng/ml), whereas BMP4 failed to do so (Figure 3D).

Taken together, we propose the following mechanism by which FK506 activates BMP signaling (see schema in Figure 3E). In the presence of BMPs at a subactivating dose, FK506 acts as inhibitor of BMP signaling. An activating dose of BMP ligand initiates receptor activation. However, reducing levels of 6 other FKBPs (FKBP12.6, FKBP13, FKBP25, FKBP54, and FKBP38) by siRNA, one at a time, did not induce BRE-luciferase activity (Supplemental Figure 2, F and G). These data are consistent with a redundancy in FKBPbs as binding partners of type I receptors. We confirmed FK506 activation of pSMAD1/5 as one read out for BMP signaling as well as others, such as pERK, pAKT, and p-c-JUN (Supplemental Figure 2, H–J).

FK506 rescues endothelial dysfunction in PAECs from patients with IPAH. To determine whether FK506 could rescue BMPR2 dysfunction in PAECs, we reduced BMPR2 protein levels to 50% of control values using RNAi (Figure 3A). As expected, these cells were unresponsive to BMP4 (10 ng/ml), but FK506 (15 ng/ml) increased ID1 in keeping with its ability to engage another type II receptor, specifically ActivinR2A (40). We then screened mvPAECs cultured from lungs harvested at transplant from 6 patients with IPAH that were obtained through the Pulmonary Hypertension Breakthrough Initiative Network. We found that mvPAECs from 3 out of the 6 patients did not increase pSMAD1/5 or ID1 in response to normally activating doses of BMP4 (10 ng/ml). One of these patients had a documented mutation in BMPR2 (c.961C>T; p.321R>R/X). In contrast, all mvPAEC cultures that did not respond to BMP4 showed an increase in pSMAD1/5 and ID1 1 hour after stimulation with FK506 (15 ng/ml) (Figure 3B). Interestingly, 4 hours after low-dose FK506 (0.2 ng/ml), ID1 mRNA was elevated, and at 8 hours, apelin mRNA was increased (Figure 3C). Apelin is regulated by BMPR2-mediated signaling (19) and is important in endothelial homeostasis. We further documented that FK506 (0.2 ng/ml) rescued dysfunction of IPAH PAECs by reversing their previously described impaired ability to form tubular networks in Matrigel (41). FK506 induced tube formation 4 hours after stimulation, in a manner comparable to that of VEGF (20 ng/ml), whereas BMP4 failed to do so (Figure 3D).

Taken together, we propose the following mechanism by which FK506 activates BMP signaling (see schema in Figure 3E). In the presence of BMPs at a subactivating dose, FK506 acts as inhibitor of BMP signaling. An activating dose of BMP ligand initiates removal of FKBP12 from the type I receptor and allows for normal SMAD- and non-SMAD–dependent signaling. When BMPR2 is mutated or dysfunctional, FK506 restores normal signaling by the dual action of removing FKBP12 from the type I receptor and inhibiting calcineurin.

Low-dose FK506 prevents hypoxic PAH in mice with deletion of BMPR2 in ECs. Next, we asked whether FK506 would prevent PAH in a mouse with BMPR2 deleted in ECs to show — as proof of concept — that FK506 could rescue downstream BMP signaling, even in the absence of a functional BMPR2 receptor. We crossed SCL-CreERTM, R26 LacZβ/β, and Bmpr2β/β mice and created an SCL-CreERTM/R26R/Bmpr2−/− (EC-Bmpr2−/−) mouse by administering 2 mg tamoxifen per day intraperitoneally for 10 days when the mice were 8–12 weeks of age. We documented BMPR2 deletion by positive LacZ staining in lung ECs (Figure 4, A and B) and in ECs of
Figure 4

Low-dose FK506 prevents the development of PAH in mice with a deletion of BMPR2 in ECs. (A and B) LacZ staining documenting BMPR2 deletion in (A) distal PAECs and (B) capillary ECs in EC-Bmpr2–/– mice. Scale bar: 100 μm. (C) Reduced BMPR2 in whole lung lysates by Western immunoblot comparing wild-type mice with tamoxifen (TAM) with floxed Bmpr2 Cre-ERT mice with or without tamoxifen. (D) Absence of Bmpr2 mRNA in ECs harvested from EC-Bmpr2–/– (KO) vs. wild-type mice (n = 3; ***P < 0.001 WT vs. EC-Bmpr2–/–, 1-way ANOVA, Dunnett's). (E) RVSP in wild-type and EC-Bmpr2–/– mice treated with vehicle or FK506 (0.05 mg/kg/d) in normoxia or hypoxia (10% O2) for 3 weeks (n = 8 per group; **P < 0.01 compared with vehicle normoxia; ***P < 0.01 vehicle hypoxia wild-type vs. EC-Bmpr2–/–, 2-way ANOVA, Dunnett’s). (F) RVH (Fulton index, weight of RV/LV and septum) in same groups as in E. (G) Representative histology of barium-injected lungs of wild-type and EC-Bmpr2–/– mice after normoxia/hypoxia with or without vehicle or FK506. The decreased number of vessels in hypoxia is ameliorated by FK506 (arrows). Scale bar: 100 μm. (H) Percentage muscularized alveolar wall and alveolar duct arteries per total arteries in wild-type and EC-Bmpr2–/– mice after normoxia/hypoxia with or without vehicle or FK506 (n = 8 mice; mean of 5 × 20 fields per mouse; **P < 0.01; ***P < 0.001 vs. normoxia wild-type and EC-Bmpr2–/–, 2-way ANOVA, Dunnett’s). (I) Arteries per 100 alveoli in same animals as in H. (J) Apelin/18S mRNA and (K) eNOS/18S mRNA in mvPAECs from EC-Bmpr2–/– mice, preconditioned in 1% hypoxia and harvested 8 hours after BMP4 (10 ng/ml) or FK506 (0.2 ng/ml) vs. vehicle (CON) (n = 3; *P < 0.05 vs. CON, 1-way ANOVA, Dunnett’s). Mean ± SEM.
Mice showed reduced BMPR2 protein expression compared with Bmpr2–/– mice from the EC-cued EC dysfunction related to loss of BMPR2, we exposed PAECs to EC-littermate controls (Figure 4D).

Male animals generally have a greater chronic hypoxia-induced pulmonary hypertensive response (42), so we used them exclusively in our study. EC-Bmpr2–/– and littermate control mice were housed in room air or in 10% oxygen (chronic hypoxia) for 3 weeks, during which time half the mice of each genotype were given a continuous s.c. infusion of low-dose FK506 (0.05 mg/kg/day) by mini-osmotic pump and the other half were given vehicle. EC-Bmpr2–/– mice and littermate controls maintained in room air had similar values for right ventricular systolic pressure (RVSP), and FK506 had no effect on this measurement. The elevation in RVSP in chronic hypoxia-exposed mice, as a measure of PAH, was more severe in the EC-Bmpr2–/– group than in controls (Figure 4E), although there was no further increase in right ventricular hypertrophy (RVH) (Figure 4F) or in vascular changes, including muscularization of distal arteries (Figure 4G, vessels marked by arrows, and Figure 4H) and loss of peripheral arteries (Figure 4I). Administration of low-dose FK506 prevented chronic hypoxic PAH in both EC-Bmpr2–/– mice and in littermate controls, as judged by lack of elevated RVSP, RVH, and reduced vascular changes. Cardiac output decreased slightly in both genotypes after chronic hypoxia independent of FK506 treatment (Supplemental Table 1). A 3-week treatment with low-dose FK506 did not increase the systemic blood pressure (Supplemental Figure 3). Despite its immunosuppressive properties, FK506, in the dose used, did not reduce total white blood cells, neutrophils, or lymphocytes (Supplemental Table 1). To address whether FK506 rescued EC dysfunction related to loss of BMPR2, we exposed PAECs from the EC-Bmpr2–/– mice to 1% O2 for 24 hours and treated the cells with low-dose FK506 (0.2 ng/ml) or BMP4 (10 ng/ml) for another 8 hours under the same conditions. An increase in apelin mRNA, an EC gene normally regulated by BMP signaling, and in endothelial nitric oxide synthase (eNOS), a gene regulated by apelin (43) and a marker of EC homeostasis were observed with FK506, but not with BMP4 (Figure 4, J and K). The same was true for cells under normoxic conditions (data not shown).

Low-dose FK506 reverses monocrotaline-induced PAH in rats, inhibits proliferation, and induces apoptosis in pulmonary artery SMCs. As patients with PAH present late in the course of their disease, we assessed whether FK506 could also reverse severe PAH and vascular pathology in an experimental model without a deletion in BMPR2. PAH was induced in adult male Sprague Dawley rats, weighing between 180 and 220 g, with a single s.c. dose of monocrotaline (60 mg). PAH was verified in a subset of animals after day 21, and a 3-week treatment with vehicle or low-dose FK506 (0.05 mg/kg/d) was initiated via s.c. mini-osmotic pump. While vehicle-treated rats showed severe PAH at day 42, FK506 treatment significantly reduced the PAH, measured by the RVSP (Figure 5A) as well as RVH (Figure 5B). The monocrotaline animal model of PAH is characterized by increased muscularity, and FK506-treated animals showed reduced muscularization compared with vehicle-treated animals (Figure 5C).

We had previously shown that FK506 could increase apelin in pulmonary artery SMCs (PASMCs). Apelin has beneficial autocrine effects on PAEC function and, by a paracrine mechanism, suppresses PASMC proliferation and can induce apoptosis (19). However, we also showed a direct effect of FK506 in inhibiting PDGF-induced PASMC proliferation (Figure 5D) and in inducing apoptosis, as judged by the caspase luminescence assay (Figure 5E). Interestingly, the latter effect of FK506 on SMCs was lost at higher immunosuppressive doses of 15 ng/ml. The mechanism appears to be pSMAD1/5 and ID1 independent (Supplemental Figure 4, A and B) and suggests an alternative pathway, possibly via PPARY and ApoE (44) or via suppression of NF-ATc, as has been previously shown (31). Using an NFAT reporter assay in PASMCs, we confirmed mild NFAT inhibition at low doses of FK506 (0.2–0.5 ng/ml) and a more pronounced effect at doses clinically used to induce immunosuppression (5–15 ng/ml) (Figure 5F). However, FK506 showed only a trend in reducing expression of IL-2, a major downstream target of NFAT signaling, when assessed in whole lung tissue of vehicle- and monocrotaline-treated rats (Figure 5G), and no effect on IFN-γ, another NFAT target (Supplemental Figure 4C). This suggests that inhibition of NFAT activation is not the major mechanism of action by which low-dose FK506 reverses PAH.

Low-dose FK506 reverses PAH related to neointima formation. Given that the monocrotaline rat model does not replicate the pathology in humans with PAH (45), we also assessed whether FK506 could reverse severe obliterative pulmonary vascular lesions characterized by neointima formation in distal pulmonary arteries. This pathology is seen in rats treated with the VEGF receptor blocker SUGEN 5416 and exposed to chronic hypoxia (46, 47). Adult male Sprague Dawley rats at 8 weeks of age, weighing between 180 and 220 g, were given a single s.c. dose of SUGEN 5416 (20 mg/kg), exposed to chronic hypoxia for 3 weeks, and then kept in normoxia for another 5 weeks (Figure 6A). This experimental protocol induces severe and progressive PAH, with extensive loss and obliteration of distal arteries associated with neointimal lesions (46). Beginning at 8 weeks, we initiated a 3-week treatment with either vehicle or low-dose FK506, by continuous subcutaneous infusion via mini-osmotic pump (0.05 mg/kg/d). Vehicle-treated rats showed severe PAH, but FK506 reversed the elevation in RVSP and RVH, resulting in values not significantly different from those of controls (Figure 6B). Cardiac output was lower after administration of SUGEN 5416 and hypoxia and increased with FK506 treatment (Supplemental Table 2). The percentage of vessels with a neointima was reduced from 60% in vehicle-treated rats to less than 20% in those administered FK506 (Figure 6C). Consistent with previous studies, we documented mild emphysema in rats treated with SUGEN 5416 and hypoxia (48, 49), reflected in a 25% decrease in the number of alveoli and a comparable reduction in the number of arteries (Figure 6D). FK506 preferentially restored arterial number so the ratio of arteries per 100 alveoli increased (Figure 6E). As in the murine chronic hypoxia experiments, FK506 also restored endothelial function, as judged by an increase in apelin (Figure 6F) in whole lung tissue. Although we cannot exclude a contribution of NFAT inhibition in FK506-mediated reversal of PAH, we found no significant reduction in targets of NFAT activation, i.e., IL-2 (Figure 6G) and IFN-γ (Supplemental Figure 5).

Discussion

We report the first high-throughput screen of known pharmaceuticals to determine whether any of these agents would increase BMPR2 signaling. Our study design permitted evaluation of strong activators (without exogenous BMP ligand), weaker acti-
Figure 5
Low-dose FK506 reverses monocrotaline-induced PAH in rats, inhibits proliferation, and induces apoptosis in PASMCs. (A) RVSP (mmHg) in rats 21 days after monocrotaline (MCT) treatment (60 mg s.c. once), with or without 3-week treatment with vehicle (VEH) or low-dose FK506 (n = 6–8; **P < 0.01 compared with VEH treated; #P < 0.05 compared with day 21 monocrotaline; §§§P < 0.001 compared with day 42 monocrotaline vehicle, 1-way ANOVA, Bonferroni post test). (B) RVH (Fulton index) in same group as above (***P < 0.001 compared with vehicle treated; §P < 0.05 compared with day 42 monocrotaline vehicle, 1-way ANOVA, Bonferroni post test). (C) Represented lung histology (Movat stain) (scale bar: 100 μm). (D) MTT proliferation assay with PASMCs in the presence or absence of PDGF (20 ng/ml) 72 hours after stimulation with vehicle (CON), BMP4 (10 ng/ml), or FK506 (0.2 and 2.0 ng/ml) (n = 5; **P < 0.01, ***P < 0.001, BMP4 vs. CON [in the presence of PDGF], 1-way ANOVA, Dunnett’s). (E) Assessment of apoptosis with measurement of caspase-3/7 luminescence under 24-hour serum starvation or treatment with BMP4 (10 ng/ml) or FK506 (0.2, 1.0, 2.0, and 15 ng/ml) (n = 5; *P < 0.05 1-way ANOVA, Dunnett’s post test). (F) Luciferase NFAT reporter activation assay in PASMCs stimulated with PDGF (30 ng/ml) and doses of FK506 between 0.2 and 15 ng/ml (##P < 0.01 and ###P < 0.001, vs. stimulation by PDGF alone, 1-way ANOVA with Bonferroni’s multiple pairs test). (G) Il2/Gapdh mRNA expression in whole lungs of rats 21 days after monocrotaline treatment (60 mg s.c. once), with or without 3-week treatment with vehicle or low-dose FK506 (n = 6–8; nonsignificant, 2-way ANOVA). Mean ± SEM.
FK506 was given following liver transplant in a patient with-associated with hemorrhagic telangiectasia (HHT), FK506 could also be of potential benefit in patients with this disorder. In fact, FK506, even at low doses, inhibits calcineurin (51). In addition, FK506 interacts with FKBP12 associ-
ated with all 3 BMPR type 1 receptors (ALK1, ALK2, and ALK3), whereas rapamycin only interacts with ALK2. Cyclosporine shares the cal-
cineurin inhibitory properties of FK506 (52), but as it does not bind FKBP12, it is a weak activator of BMP signaling in PAECs.

Also on the list of BMPR2 signaling activators is the TGF-β receptor blocker, SB431542, which could also antagonize the enhanced TGF-β signaling that occurs when BMPR2 is deficient (53). Our libraries contained pharmaceuticals currently used to treat PAH, including bosentan, iloprost, and inamidine. None activated BRE-luciferase, although iloprost can induce ID1 by a pSMAD1/5-independent, cAMP-mediated mechanism (54). Recent data suggest that other medications approved and effective for PAH, such as the vasodilator and phosphodiesterase inhibitor sildenafil, can partially restore BMPR2 defective signaling (55), underscoring the importance of this pathway in PAH.

Both at immunosuppressive and at low doses, FK506 not only mimics BMP4 signaling in PAECs but also promotes PAEC survival and increases tube formation, functions essential for preventing loss of vessels and inducing vessel regeneration in PAH (56). In addition, we have evidence of both paracrine (via apelin) (57) and autocrine effects of FK506 in reducing proliferation and mediating apoptosis in SMCs.

TGF-β type I family receptors (including ALK3) share a common glycine-serine–rich sequence, identified as the site of phos-
phorylation by type 2 receptors as well as the FKBP12 binding site (58). FKBP12 has multiple functions, including Ca++ channel gating and protein folding (37). By serving as a docking protein for the phosphatase calcineurin (39), FKBP12 also modulates the phosphorylation status of TGF-β type I and other receptors, e.g., EGF-R and inositol trisphosphate receptors (50), providing a safeguard against leaky constitutive signaling (37). We showed that FK506 interacts with FKBP12 and is able to dissociate it from type I receptors, e.g., ALK1, ALK2, and ALK3 that form heterodimers with BMPR2. This is a novel finding, although the concept that FK506 can release bound FKBP12 from TGF-β type I receptors or EGF-R (59) has been described previously. Furthermore FK506, even at low doses, inhibits calcineurin activity, which, in concert with removing FKBP12, results in phosphorylation of ALK1, ALK2, and ALK3 and in downstream pSMAD1/5-dependent and -independent signaling. Phosphory-
lation of the type I receptor induced by FK506 requires kinase activity from a type 2 BMP receptor, and the type I receptor likely co-opts ActivinR2A when BMPR2 is reduced or dysfunctional. Thus, signaling is transduced in mice with deletion of BMPR2 in ECs and in human PAECs with mutant BMPR2.

FK506 also increases EC expression of ALK1 and endoglin (60). As loss-of-function mutations in these genes are observed in PAH associated with hemorrhagic telangiectasia (HHT), FK506 could also be of potential benefit in patients with this disorder. In fact, FK506 was given following liver transplant in a patient with HHT who had multiple arteriovenous malformations, and it was noted that internal and external telangiectases, epistaxes, and anemia disappeared, suggesting that the mechanism of action of FK506 involved partial correction of endoglin and ALK1 haplo-
insufficiency (60).

Binding and removing FKBP12 from the type I receptors by FK506 is dynamic and varies with different FK506 concentrations at different time points (data not shown), so the effect, particularly, of low-dose FK506 is unlikely to induce the same constitutive activation of BMP signaling that is observed in fibro dysplasia ossi-
ficans progressiva. This is a condition characterized by a mutation in ALK2 that permanently reduces binding of FKBP12 (61).

Low-dose FK506 reverses the impaired ability of PAECs from patients with IPAH to form tubular networks (41, 62), consist-
tent with its induction of apelin, a pSMAD-independent target of BMPR2 signaling (19). Apelin (63), a ligand for the G protein-coupled receptor APJ, is highly expressed in endothelial but not in other vascular cells (64). It is proangiogenic (65) and induces eNOS (57). Apelin-null mice develop more severe hypoxia-induced PAH than controls. Patients with IPAH have reduced apelin plasma levels (43), and their PAECs have decreased apelin mRNA and protein (19). Furthermore, the role of apelin in raising lev-
els of a miRNA that represses FGF production is thought to be responsible for the paracrine effect of apelin in suppressing SMC proliferation and inducing SMC apoptosis. This may be the mech-
anism causing reversal of PAH in both the monocrotaline and the SUGEN hypoxia rat models (60), but we also showed that low-dose FK506 represses cultured PASMC proliferation and induces apop-
tosis independent of endothelial apelin.

Our studies show efficacy of low-dose FK506 in activating the BMPR2 pathway. Interestingly, it was this dose in contrast to a higher dose that inhibited atherosclerotic plaque development and progression in ApoE−/− mice (33, 34). Moreover, high doses of FK506 (>10 fold of those used in our study) caused systemic hypertension and transplant vasculopathy in animal models, presumably mediated by a paradoxical decrease in eNOS and increase in endothelin production (67). In contrast, the low-dose FK506 used in our studies did not induce systemic hypertension, even after a 3-week treatment.

We chose mice with deletion of BMPR2 in ECs to determine whether FK506 could prevent hypoxia-induced PAH in the absence of endothelial BMPR2 and found that it was effective in both EC-Bmpr2−/− and wild-type genotypes. The latter may be related to reversal of hypoxia-mediated suppression of BMPR2 signaling (68).

Our study is one of few to show that an agent can reverse severe established PAH and neointima formation in the SUGEN5416/hypoxia rat model (46, 66). We suggest that FK506 was able to do so both by upregulating apelin and, to a lesser extent, by sup-
pressing NFAT–mediated gene regulation. The effect of inhibiting NFAT activation, in addition to increasing BMPR2 signaling, would be beneficial in treating PAH. Previous studies have shown that inhibition of NF-ATc with rapamycin reverses monocrotaline-induced PAH (31) by restoring Kv1.5 channel expression, decreasing proliferation, and inducing apoptosis of SMCs.

Treatment with FK506 increases cardiac output in the SUGEN5416/hypoxia rat model, perhaps because the interaction of FK506 with FKBP5 modulates calcium cycling in the heart. In a mouse model of left heart failure, characterized by increased expression of FKBP12.6 in the heart, FK506 restored contractile function of isolated cardiomyocytes by inhibiting the association with FKBP12.6 and the ryanodine receptor (69).
improving BMP signaling could be valuable in treating PAH as well as other vascular and nonvascular diseases, including cancer, in which BMP signaling is reduced, and bone grafting or spinal fusion surgery, in which activation of BMP is required for a successful result (70, 71).

In conclusion, we used a high-throughput screen to identify a compound, FK506, that is able to activate BMPR2-mediated signaling and endothelial-specific gene regulation (e.g., apelin), even in the absence of exogenous ligand and BMPR2. The efficacy of low-dose FK506 in improving BMP signaling could be valuable in treating PAH as well as other vascular and nonvascular diseases, including cancer, in which BMP signaling is reduced, and bone grafting or spinal fusion surgery, in which activation of BMP is required for a successful result (70, 71).

**Figure 6**
Low-dose FK506 reverses established PAH and neointima formation in rats. (A) Timeline of experiments. (B) RVSP and RVH (Fulton index) in rats in normoxia with or without vehicle (VEH) or FK506 and in rats after SUGEN with 3 weeks hypoxia and 5 weeks normoxia, sacrificed at 8 weeks and at 11 weeks following treatment with vehicle or FK506 (n = 8; *P < 0.05; ***P < 0.001 vs. same condition in normoxia, 2-way ANOVA, Bonferroni post test). (C) Representative images (scale bar: 100 μm) and percentage vessels with neointima in hypoxia/SUGEN/normoxia rats at 8 and 11 weeks treated with vehicle or FK506 (n = 8; **P < 0.01 vs. vehicle, 1-way ANOVA, Bonferroni post test). (D) Number of alveoli per mm² in normoxia (with or without vehicle or FK506) and in rats after hypoxia/SUGEN/normoxia, sacrificed at 11 weeks (with or without 3-week treatment of vehicle or FK506) (n = 8; *P < 0.05 vs. untreated normoxia condition, 2-way ANOVA, Dunnett’s post test). (E) Mean number of arteries per 100 alveoli (5 fields ×20) in same groups as in D (n = 8, #P < 0.05, 1-way ANOVA, selected pairs post test, vehicle vs. FK506). (F) Apelin/β-actin mRNA expression in total lung lysate in same group as in D (n = 8; *P < 0.05, 1-way ANOVA, Dunnett’s post test). (G) Il2/Gapdh mRNA expression in whole lungs of rats in normoxia (with or without vehicle or FK506) and in rats after hypoxia/SUGEN/normoxia, sacrificed at 11 weeks (with or without 3-week treatment of vehicle or FK506) (n = 8; *P < 0.05 vs. vehicle normoxia, #P < 0.05 vs. FK normoxia, nonsignificant trend in decrease of IL-2 with FK506 treatment, 2-way ANOVA, Bonferroni multiple-comparison test). Mean ± SEM.
Methods

High-throughput screen. Libraries of FDA-approved drugs and bioactive compounds, containing 3,756 unique compounds (NIH-CC, LOPAC, Biomol ICCB Known Bioactives, Microsource spectrum, Biomol FDA-approved drug library), were available from the High-Throughput Bioscience Center at Stanford University. The C2C12 mouse myoblast cell line that stably expresses a BMP response element from the ID1 promoter linked to luciferase (BRE-luc) (25) was used as a reporter cell line for BMP activation. The bioassay can detect luciferase activity after stimulation with a dose as low as 3 pM BMP4 (our ligand of choice, due to the excellent assay sensitivity) (see Supplemental Figure for details).

Reagents. FK506 (Cayman Chemicals), rapamycin (Cayman Chemicals), cyclosporine (Sigma-Aldrich), shield-1 (a gift from T.J. Wandless, Stanford University), SUGEN5416 (Cayman Chemicals), BMP4 (Sigma-Aldrich), and monocrotaline (Sigma-Aldrich) were used.

Plasmids. FKB12-Flag plasmid was a gift from Takeshi Imamura (JFCR Cancer Institute, Tokyo, Japan). HA-ALK1, HA-ALK2, HA-ALK3 have been previously described (72).

Transcription reporter assays. C2C12 cells were seeded in 24-well plates and then transfected with Polyethylenimine (PEI, Fermentas) with the indicated plasmids. For CAGA-Luc, the luciferase activity was analyzed 24 hours after stimulation with TGF-β3 (5 ng/ml) or FK506 with indicated concentrations. For BRE-luc, the transfected cells were pretreated with LDN-193189 (120 nM) for 30 minutes before stimulation with FK506 (1 μg/ml) for 24 hours. Each experiment was performed in triplicate at least, with normalization to β-galactosidase activity.

Cell culture. C2C12 mouse myoblastoma cell line was stably transfected with a construct in which the BMP/SMAD elements of the ID1 promoter were linked to luciferase (BRE-luc) (a gift from Peter ten Dijke). C2C12 and 293T were maintained in DMEM supplemented with 10% FBS, penicillin/streptomycin, and Glutamine (Gibco). Human large PAECs (ScienCell) and human and mouse mvPAECs were grown in commercial EC media (ScienCell). Cells were subcultured at a 1:3 ratio in gelatin-coated dishes. Human PASMcs (Lonza) were grown in commercial SMC media (Lonza) and subcultured at a 1:5 ratio. Only passages 3–8 were used.

Immunoprecipitation and immunoblotting. 293T cells were transfected with indicated plasmids, medium was changed 12 hours after transfection, and, 48 hours after transfection, cells were stimulated with FK506 (100 ng/ml) for 30 minutes (see the Supplemental Methods for details).

Isolation of human and mouse mvPAECs. Human and murine mvPAECs were isolated from digested whole lung tissue using CD31 antibody–coated magnetic beads (Dynabeads; Invitrogen) as previously described (19).

mRNA expression by qRT-PCR. Total RNA was extracted and purified from whole lung tissue and cells with the RNAeasy Plus Kit (Qiagen) and then reverse transcribed using SuperScript III (Invitrogen) per the manufacturer’s instructions. Expression levels of selected genes were quantified using preverified Assays-on-Demand TaqMan primer/ probe sets (Applied Biosystems) and normalized to ribosomal RNA 18S and B2M (mice and humans) and β-actin and Gapdh (rats). The housekeeping gene that was chosen was most consistent throughout the experimental conditions.

Western Immunoblotting. Western immunoblotting was done as previously described (41).

Apoptosis assay and proliferation assays. PAEC, mvPAEC, and PASMC survival and proliferation were assessed by cell counts and MTT assays. Caspase-3/7 (Promega) was used to detect apoptosis as previously shown (19, 41).

RNAi. siRNAs for BMPR2 (Dharmacon) were transfected into PAECs using RNAi Max (Invitrogen) as described previously (73). The knockdown efficiency for BMPR2 was determined by Western immunoblotting. siRNAs for BMPR2, ActivinR2A, Activin R2B, ALK1, ALK2, ALK3, and FKB12 were transfected into C2C12 BRE-luc cells using DharmaFect3, and knockdown efficiency was determined by qRT-PCR. Nontargeting siRNA (Dharmacon) was used as a control.

Tube formation assay. PAECs were starved for 12 hours in 0.2% FBS, and 10,000 cells were seeded on Matrigel (Trevigen) in serum-free medium with or without stimuli. The number of tubes and tube length were assessed after 8 hours in large PAECs and after 4 hours in mvPAECs.

Creation of cell-specific inducible EC-Bmpr2−/− mice. Endothelial SCL-CRE ER² mice, with a S-endothelial SCL enhancer (~7 to 0.9 kb) that directs expression to endothelium (74), were crossed with Rosa26R mice and crossed with Bmpr2−/− mice created previously in our laboratory. Tamoxifen was given at 2 mg per day i.p. for 10 days; after another 14 days, CRE activation led to a deletion in Bmpr2 in ECs in lungs as well as all other vascularized tissues. Littermates were used as controls.

Hypoxia/SUGEN/normoxia and monocrotaline rat models. Adult male Sprague Dawley rats at 8 weeks of age, weighing between 180 and 220 g, were given a single s.c. dose of SUGEN5416 (20 mg/kg) and then placed in chronic hypoxia for 3 weeks, followed by a period of 5 weeks normoxia, as previously described (46). The monocrotaline experiments in rats were carried out as previously described (75).

Statistics. All data are presented as mean ± SEM. We performed the statistical analyses using 1-way ANOVA when more than 2 groups of data were compared and 2-way ANOVA when 2 conditions were involved. We considered differences to be statistically significant at P < 0.05.

Study approval. All animal experiments were reviewed and approved by the Stanford University IACUC in accordance with the guidelines of the NIH. The studies on human primary cells were approved by the appropriate Institutional Review Board on human subjects and IACUC at Stanford University.

Acknowledgments
