*J Clin Invest.* 2014;124(12):5481-5489. [https://doi.org/10.1172/JCI78765](https://doi.org/10.1172/JCI78765).

Increased synthesis of cervical hyaluronan (HA) from early to late pregnancy has long been proposed to play an essential role in disorganization of the collagen-rich extracellular matrix to allow for maximal compliance and dilation of the cervix during the birth process. Here, we show that HA is not essential for increased cervical distensibility during late pregnancy. Rather, cervicovaginal HA plays an unanticipated important role in epithelial barrier protection of the lower reproductive tract. Specifically, HA depletion in the cervix and vagina resulted in inappropriate differentiation of epithelial cells, increased epithelial and mucosal permeability, and strikingly increased preterm birth rates in a mouse model of ascending vaginal infection. Collectively, these findings revealed that although HA is not obligatory for cervical compliance, it is crucial for maintaining an epithelial and mucosal barrier to limit pathogen infiltration of the lower reproductive tract during pregnancy and thereby is protective against infection-mediated preterm birth.

Increased synthesis of cervical hyaluronan (HA) from early to late pregnancy has long been proposed to play an essential role in disorganization of the collagen-rich extracellular matrix to allow for maximal compliance and dilation of the cervix during the birth process. Here, we show that HA is not essential for increased cervical distensibility during late pregnancy. Rather, cervicovaginal HA plays an unanticipated important role in epithelial barrier protection of the lower reproductive tract specifically. HA depletion in the cervix and vagina resulted in inappropriate differentiation of epithelial cells, increased epithelial and mucosal permeability, and strikingly increased preterm birth rates in a mouse model of ascending vaginal infection. Collectively, these findings revealed that although HA is not obligatory for cervical compliance, it is crucial for maintaining an epithelial and mucosal barrier to limit pathogen infiltration of the lower reproductive tract during pregnancy and thereby is protective against infection-mediated preterm birth.

Introduction

Preterm birth (PTB) affects 11.7% of all pregnancies in the United States. Worldwide, PTB is the primary cause of infant morbidity and mortality in the first postnatal weeks of life and a risk factor for lifelong health problems in those that survive (1). Of the known causes for PTB in women, infection accounts for the largest percentage (25%–40%) of spontaneous PTB. Ascending microbes from the vagina and cervix are thought to be the primary route for infection. Prophylactic antimicrobial treatment of women has not decreased PTB rates, which suggests that the factors predisposing to infection-mediated preterm birth are not confined to the microbe composition of the reproductive tract (2, 3). Parturition, the process of birth, requires timely orchestration of multiple processes that include uterine contractions and remodeling of the cervix from closed and rigid to soft and compliant. Throughout pregnancy, the cervix must protect the fetus from external insults, such as ascending infection from the vagina through the cervix; provide structural integrity for maintenance of pregnancy; and simultaneously undergo progressive remodeling to a distensible organ to allow a safe birth. Regardless of cause, cervical changes precede onset of term and preterm labor in both women and mice (4, 5); thus, defining the mechanisms of cervical remodeling in term birth and PTB will allow for improved detection and prevention.

Hyaluronan (HA) is a nonsulfated glycosaminoglycan (GAG) found ubiquitously in the extracellular matrix of all mammalian tissues. During physiologic pregnancy and preterm labor in women and mice, HA levels increase significantly in the cervix (6–10). HA is synthesized by cervical fibroblasts, epithelial cells, and immune cells and released into the extracellular matrix (ECM) and cervicovaginal mucus. Beginning in early pregnancy, increased synthesis and deposition of collagen with reduced cross-links, along with declined synthesis of specific matricellular proteins, correlates with a significant increase in distensibility by gestation day 12 (d12) in the mouse cervix (11). At the end of pregnancy, increased expression of the HA synthase 2 (Has2) gene, and consequent increases in epithelial and stromal HA, correlate with maximal cervical distensibility, collagen disorganization, and hydration of the cervix (10). In mice, HA at term pregnancy accounts for 1% of the dry cervical mass, a 5-fold increase compared with early pregnancy (9). Cervical HA is also increased in mouse models of infection-mediated and non-infection-mediated PTB, although expression is limited to the stromal matrix (9). In addition to its structural role in the ECM, HA has diverse functions such as cell growth, migration, adhesion, and differentiation that are dependent on HA size and expression of HA-interacting molecules such as CD44, versican, and inter-alpha-trypsin inhibitor (12). The increase in both high- and low-molecular weight HA and cell-specific expression of HA-binding partners in the term cervix suggest that HA may have additional functions in cervical remodeling during parturition that remain to be elucidated (6).

The objectives of our present study were to evaluate the functions of cervical HA during pregnancy and infection-associated PTB using a tissue conditional transgenic mouse model devoid of HA in reproductive tissues. We tested the hypothesis that the increase in cervical HA at the end of pregnancy leads to maximal cervical distensibility and collagen disorganization that is crucial for a successful parturition, and also evaluated the role of HA in cervical epithelial function in term birth and infection-mediated PTB.

Results

Conditional HA-depleted mouse models. To evaluate the specific functions of HA in cervical remodeling, we crossed mouse lines

with global and tissue-specific KO of the 3 genes that encode HA synthase (Has1, Has2, and Has3) to generate mice in which HA was depleted in the female reproductive tract (see Methods). Targeted mutations in Has2 result in embryonic lethality (13), whereas mice with global double-KO of Has1 and Has3 (referred to herein as Has1/3 KO) develop and grow normally (14, 15). To achieve HA depletion in the reproductive tract, we used a Has2fl/fl and heterozygous progesterone receptor Cre knockin cross (Has2fl/fl;PR-Cre+/– mice; referred to herein as Has2 KO) (16). In the Has2 KO mice, progesterone receptor Cre was expressed throughout the reproductive tract in both epithelia and stroma of the uterus and cervix (Supplemental Figure 1; supplemental material available online with this article; doi:10.1172/JCI78765DS1). Crossing Has1/3 KO mice with Has2 KO mice resulted in mice with reproductive tract HA depletion (referred to herein as Has1/2/3 KO mice). Cervical HA content, assessed by fluorophore-assisted carbohydrate electrophoresis (FACE), was decreased on average 93% in Has2 KO mice and 95% in Has1/2/3 KO mice (Figure 1A). Loss of Has2 gene expression was not compensated with upregulation of Has1 or Has3 in cervices of Has2 KO mice (Figure 1B). Immunofluorescence staining of HA revealed that on d18, the Has1/2/3 KO cervical epithelia and mucus were completely devoid of HA, with low levels of HA in stroma (Figure 1, C and D). While immunofluorescence revealed cell localization of insoluble HA that was bound to other ECM structures or to cells, the majority of HA in the cervix was soluble (>93% in WT mice) and could be removed from the sections during the staining procedure (Supplemental Figure 2).

Parturition rates and cervical ripening. The increase of hydrophilic, high-molecular weight HA (500 to ≥2,000 kDa) during cervical ripening has been proposed to play an important role in promoting tissue hydration and collagen matrix disorganization in the cervical stroma, making HA essential for the final changes in tissue compliance required for birth (6, 17). Given HA’s established function as a structural molecule important in tissue hydration in other ECM-rich tissues, we anticipated that the cervix of HA-depleted mice would fail to undergo reorganization of the collagen matrix, resulting in a parturition defect. Surprisingly, lack of HA did not affect the time of delivery (Table 1), which suggests that cervical HA is not required for normal ripening. Moreover, HA depletion did not affect parity, the increase in hydration during cervical ripening, pubic symphysis elongation, or litter size (Supplemental Table 1).

Timing of parturition was neither premature or delayed by targeted loss of Has2, as pregnant Has2 KO and Has1/2/3 KO mice delivered on time (i.e., between 6:00 PM on d18 and 12:00 PM on d19), similar to WT and Has1/3 KO females.

KO cervix. Thus, loss of epithelial HA increased susceptibility to
infection-induced PTB. This increased susceptibility was dependent on loss of Has2, as PTB rates of Has1/3 KO and WT mice were similar (Table 2). The increased sensitivity to infection in HA-depleted mice was accompanied by a more robust inflammatory response, with marked increases in gene expression of both classical and alternatively activated macrophage markers in Has1/2/3 versus WT cervix (Figure 6). Neither oral administration nor vaginal application of HA (200 μg/d on di2–di7) rescued E. coli–induced PTB in the Has1/2/3 KO mice (Supplemental Figure 4A). The failure to rescue may be due to the fact that neither

PTB rates after vaginal exposure to live E. coli (10^7 and 10^8 CFU) or systemic LPS (1 μg/mouse i.p.) on d16. *P < 0.05 vs. WT, Fisher exact test.
The integument of the mucosal barrier was assessed by placement of polyethylene glycol–coated (PEG-coated) polystyrene microparticles (PSPEGs) that were larger in diameter than the mucus pore spacing, but similar in size to \( E. coli \) (1 \( \mu \)m), into the mouse cervicovaginal canal on d17. Particles densely coated with PEG have mucoinert surfaces, such that coated particles smaller in diameter than the mucus pores were able to penetrate human and mouse cervicovaginal mucus (21, 22). However, if the mucus pore spacing is smaller than the particle diameter, even mucoinert particles will become sterically trapped in the mucus mesh (21). At 15 minutes after application of 1 \( \mu \)m PSPEGs into the vagina, similar fractions traversed into the uterus in both WT and \( \text{Has1/2/3} \) KO mice; however, in both genotypes, the majority of the PSPEGs were retained in the cervicovaginal canal (Figure 7B). Higher-magnification images in the ectocervical areas did reveal differences in PSPEG movement: the particles moved deeper into the mucosal layer in \( \text{Has1/2/3} \) KO versus WT mice, appearing closer to epithelia (Figure 7B). The substantial difference in penetration of mucus by the PSPEGs, which were similar in size to bacteria, suggests that HA within the cervicovaginal mucus plays a role in mucosal barrier protection from pathogens.

**Discussion**

Although a substantial number of PTBs in women are associated with ascending infection from the vagina through the cervix, no specific microbe or microbiome profile has been shown to be causative of PTB, and prophylactic antibiotic treatment during or prior to pregnancy does not alter PTB rates (23, 24). Our present findings offer a rationale for previous observations and provide new insights into the importance of the cervical epithelia and mucus to form a protective barrier against pathogen invasion, especially...
HA secreted by the epithelia plays key roles in barrier function. These roles include regulation of epithelial cell differentiation and organization as well as modulation of cervical mucous permeability. The lower expression of the junctional protein occludin and its receptor, CD44, is likely critical for epithelial differentiation and barrier function. This notion is supported by the fact that squamous epithelial cells, such as keratinocytes, are also dependent on CD44 for normal cellular function. Cd44−/− mice have skin permeability dysfunction, and HA-CD44 interactions are required for mediating intracellular signaling pathways necessary for keratinocyte migration, adhesion, proliferation, and differentiation (27, 28).

A second novel finding of the current study is that HA within the stromal ECM was not essential for collagen disorganization and increased hydration of the cervix during the accelerated phase of cervical ripening at the end of pregnancy. During extensive remodeling of the cervix during late gestation, HA secreted by the epithelia plays key roles in barrier function. These roles include regulation of epithelial cell differentiation and organization as well as modulation of cervical mucous permeability. The lower expression of the junctional protein occludin observed in CD44− epithelial cells of HA-depleted mice (Figure 5, Supplemental Figure 3, and Supplemental Table 3) suggests that HA affects the protein expression and/or subcellular distribution of adhesion/junction molecules, rather than the transcription of these genes. Our observations that HA was necessary for appropriate differentiation of the cervical epithelia, and that its depletion within the cervicovaginal mucosal epithelia increased the vulnerability to microbe-induced PTB, endorse the importance of HA synthesis in the epithelia in maintenance of pregnancy. This function expands HA’s proposed role in protection of mucosal epithelia, as a recent study reported the importance of HA in breast milk to activate antimicrobial expression in gut mucosal epithelia of the offspring ingesting the milk (25).

The fact that vaginal HA application from d12 to d17 failed to rescue the sensitivity to PTB in Has1/2/3 KO mice, as well as the failed restoration of permeability in HA-treated ECT-1 cells with siRNA-mediated Has3 knockdown, suggest that HA function is more complex than simply improving the barrier properties of the mucus. It is possible that the program of cell differentiation of basal epithelia may require HA exposure specifically to the basal epithelia, which is likely not efficient with vaginal HA application, or that exposure may be required at earlier time points in pregnancy. Our present data indicated that the absence of HA leads to abnormal differentiation and epithelial layer organization and altered mucosal properties that lead to declined barrier function. Barrier function encompasses both the mucosal barrier properties and the paracellular regulation between epithelial cells regulated by junctional proteins. Differences in the biophysical characteristics of cervical mucus from women at high risk of PTB supports the importance of mucosal properties in barrier function (26). Given that transcript expression of mucins, antimicrobial peptides, tight junctions, and adherens junctions were similar between d18 WT and HA-depleted cervixes, the function of HA and its binding partners in cervical epithelial function and cell signaling remains to be elucidated. The observed regional and differentiation-specific differences in expression of occludin and E-cadherin protein suggest that epithelial barrier function is compromised, although further studies are required to understand HA’s role. Although numerous HA-interacting molecules are expressed in the pregnant cervix to modulate HA function, we propose that the interaction of HA with its receptor, CD44, is likely critical for epithelial differentiation and barrier function. This notion is supported by the fact that squamous epithelial cells, such as keratinocytes, are also dependent on CD44 for normal cellular function. Cd44−/− mice have skin permeability dysfunction, and HA-CD44 interactions are required for mediating intracellular signaling pathways necessary for keratinocyte migration, adhesion, proliferation, and differentiation (27, 28).

A second novel finding of the current study is that HA within the stromal ECM was not essential for collagen disorganization and increased hydration of the cervix during the accelerated phase of cervical ripening at the end of pregnancy. During extensive remodeling of the cervix during late gestation, HA secreted by the epithelia plays key roles in barrier function. These roles include regulation of epithelial cell differentiation and organization as well as modulation of cervical mucous permeability. The lower expression of the junctional protein occludin observed in CD44− epithelial cells of HA-depleted mice (Figure 5, Supplemental Figure 3, and Supplemental Table 3) suggests that HA affects the protein expression and/or subcellular distribution of adhesion/junction molecules, rather than the transcription of these genes. Our observations that HA was necessary for appropriate differentiation of the cervical epithelia, and that its depletion within the cervicovaginal mucosal epithelia increased the vulnerability to microbe-induced PTB, endorse the importance of HA synthesis in the epithelia in maintenance of pregnancy. This function expands HA’s proposed role in protection of mucosal epithelia, as a recent study reported the importance of HA in breast milk to activate antimicrobial expression in gut mucosal epithelia of the offspring ingesting the milk (25).

The fact that vaginal HA application from d12 to d17 failed to rescue the sensitivity to PTB in Has1/2/3 KO mice, as well as the failed restoration of permeability in HA-treated ECT-1 cells with siRNA-mediated Has3 knockdown, suggest that HA function is more complex than simply improving the barrier properties of the mucus. It is possible that the program of cell differentiation of basal epithelia may require HA exposure specifically to the basal epithelia, which is likely not efficient with vaginal HA application, or that exposure may be required at earlier time points in pregnancy. Our present data indicated that the absence of HA leads to abnormal differentiation and epithelial layer organization and altered mucosal properties that lead to declined barrier function. Barrier function encompasses both the mucosal barrier properties and the paracellular regulation between epithelial cells regulated by junctional proteins. Differences in the biophysical characteristics of cervical mucus from women at high risk of PTB supports the importance of mucosal properties in barrier function (26). Given that transcript expression of mucins, antimicrobial peptides, tight junctions, and adherens junctions were similar between d18 WT and HA-depleted cervixes, the function of HA and its binding partners in cervical epithelial function and cell signaling remains to be elucidated. The observed regional and differentiation-specific differences in expression of occludin and E-cadherin protein suggest that epithelial barrier function is compromised, although further studies are required to understand HA’s role. Although numerous HA-interacting molecules are expressed in the pregnant cervix to modulate HA function, we propose that the interaction of HA with its receptor, CD44, is likely critical for epithelial differentiation and barrier function. This notion is supported by the fact that squamous epithelial cells, such as keratinocytes, are also dependent on CD44 for normal cellular function. Cd44−/− mice have skin permeability dysfunction, and HA-CD44 interactions are required for mediating intracellular signaling pathways necessary for keratinocyte migration, adhesion, proliferation, and differentiation (27, 28).

A second novel finding of the current study is that HA within the stromal ECM was not essential for collagen disorganization and increased hydration of the cervix during the accelerated phase of cervical ripening at the end of pregnancy. During
cervical ripening, HA is produced in a range of sizes from low to high molecular weight. High-molecular weight HA has a well-established function as a structural molecule that increases tissue flexibility, elasticity, and/or resilience: it can form cross-links with the proteoglycan versican to generate structures that are space-filling and increase elasticity of a tissue while maintaining tissue strength. HA has been proposed to be directly linked with ECM disorganization in the term cervix of many species. While collagen bundles were more closely packed in HA-depleted mice, suggesting that HA is involved as a space-filling molecule, collagen fibril size and resulting tissue mechanical strength were not affected (Figure 2). However, our present studies only evaluated cervical stiffness, and it remains possible that HA loss in the cervix may affect other biomechanical parameters, such as recoverability of the tissue (elasticity) or its ability to resist fracturing and breaking (strength). Low-molecular weight HA has proposed immunomodulating functions that include recruitment and activation of leukocytes. HA depletion did not alter the induction of either classical or alternatively activated macrophages; rather, the gene expression response was similar between WT and Has1/2/3 KO mice (Figure 6).

Globally, PTB and stillbirths associated with PTB result in 3.3 million perinatal deaths per year (29). While the direct causes of PTB remain unknown, the primary risk factors for PTB and resulting perinatal death in developing countries are poor nutrition and infection. Despite the magnitude of this health problem, there are few effective strategies for diagnosis or prevention of PTB. The unanticipated role of HA as a protective factor against pathogen-mediated PTB warrants further studies to determine whether reduced cervical HA expression (or increased HA metabolism) may be a susceptibility factor predisposing certain women to infection-associated PTB and whether long-term exogenous HA may reduce risk of infection-mediated PTB. Such findings could readily be translated into cost-effective preventative therapies.

**Methods**

*Mice. Has1−/−* mice (14) and *Has3−/−* mice (15) were generated previously using a strategy that eliminates the catalytic site of each enzyme. Has1−/− and Has3−/− mice were intercrossed to generate Has1/3 KO animals, nullizygous for both alleles. Has2fl/fl mice (30) were crossed with PR-Cre−/− mice (16). Has1/3 KO and Has2fl/fl PR-Cre−/− mice were backcrossed 5 times to generate Has1/2/3 KO mice. Mice were housed under a 12-hour light/12-hour dark photoperiod at 22°C and were of mixed strain (C57BL/6×129Sv). Mice in these studies were 2–6 months old and nulliparous. Female mice were housed with males from 4:00 PM to 8:00 AM, then checked for vaginal plugs. The day of plug formation was counted as d0, and birth occurred on d19. Deliveries between 6:00 PM on d18 to 12:00 PM on d19 was considered term (i.e., on time). Tissues from pregnant mice were collected at midday except for d18 samples, which were collected in the evening closer to the time of delivery.

The mouse colony was maintained under clean/sterile conditions, and the health status of mice was assessed on a quarterly basis. Based on tests using sentinel mouse serum, the colony was negative for *Mycoplasma pulmonis*, epizootic diarrhea of infant mice (EDIM), Theiler’s murine encephalomyelitis virus (TMEV), pinworms, mouse hepatitis virus (MHV), parvoviruses (MVM and MPV), Sendai virus, and fur mites.

**Tissue collection.** Pubic symphysis length was measured using a digital caliper on mice after removing the abdominal wall. Cervices were isolated by dissection at the uterocervical junction, and all vaginal tissue was removed. Wet weights of cervical tissues were collected after tissue dissection. For immunostaining, cervices with vagina and uterine horns were collected for longitudinal sections with the cervical canal throughout each section and in the same longitudinal plane as the uterine horns.

**Infection-induced PTB by vaginal *E. coli* inoculation.** Live *E. coli* (serotype O55; ATCC) (20 μl bacteria equal to 10^5 to 10^7 CFU) was inoculated into vagina the morning of d16, and mice were observed for 48 hours for signs of PTB as described previously (31). To confirm the dose of bacteria given, an aliquot of the leftover bacteria (5 × 10^5 CFU/ml) was serially diluted 1:100 to bring down the bacteria concentration to 500 CFU/ml. A 100-μl aliquot was plated under sterile conditions, and...
colonies were counted after overnight incubation at 37°C to confirm the accuracy of the CFU. For mice receiving daily vaginal HA (20 μl HA equal to 100 μg; intrinsic viscosity, 2.7-3.6 m²/kg; molecular weight, 1.7-2.4 kDa; catalog no. HA-EP3.0, Stanford Chemicals), the HA was placed in the cervicovaginal canal on the evenings of d12-d17.

Infection-induced PTB by systemic LPS injection. Preterm labor was induced by i.p. injection of 100 μL LPS ranging 1-100 μg (strain O:55, Sigma-Aldrich) on d16 in WT and HA-depleted mice. Animals were observed 48 hours after injection for signs of PTB.

FACE. Cervices were collected, and dry weight was measured after lyophilization. Tissues were digested in 100 mM ammonium acetate with 0.0005% phenol red (pH 7.0) containing 0.25 mg/ml proteinase-K (Roche) for 4 hours at 60°C. Proteinase-K was inactivated by boiling, and undigested tissues were pelleted by centrifugation. An aliquot of 12.5 μl supernatant equal to 0.125 mg dry weight of digested cervix was processed for FACE as described elsewhere (31, 32), with minor modifications. HA and chondroitin/dermatan sulfate (CS/DS) disaccharides were generated by digestion with Hyaluronidase SD (10 mU) at 37°C and Chondroitinase ABC (10 mU) for 2 hours to allow for elution of soluble HA. After centrifugation at 10,000 g for 10 minutes, supernatants were transferred to fresh tubes. The pellets were washed once and dispersed in ammonium acetate buffer (5 mg wet tissue/100 μl buffer). Proteinase K (0.5 mg/ml; Roche) was added to pellet and supernatant and digested for 4 hours at 60°C. Proteinase K was inactivated by boiling and centrifuged at 10,000 g for 10 minutes. An aliquot of 25 μl sample was processed for FACE analysis as described above.

Immunostaining. Unless otherwise stated, mice were perfused with 4% paraformaldehyde (Sigma-Aldrich) in PBS, and harvested reproductive tracts were fixed in 4% paraformaldehyde overnight and kept in PBS until paraffin embedding. Sections (5 μm thick) were deparaffinized and preincubated with 10% normal donkey serum (Life Technologies) for 20 minutes at room temperature. Subsequently, tissue sections were incubated with 10% donkey serum containing primary antibody, biotinylated HA binding protein (5 μg/ml; Seikagaku), oculdin (1:200 dilution; catalog no. 31721, Abcam), E-cadherin (1:200 dilution; catalog no. 3195, Cell Signaling), CD44 (5 μg/ml; catalog no. MAB2137, Chemicon), TFF1 (1:200 dilution; catalog no. Tff1-A, Alpha Diagnostic), or Ki67 (catalog no. VP-K452, Vector labs) in 10% normal donkey serum for approximately 16 hours at 4°C. The slides were washed 3 times with PBS, then incubated with a solution containing fluorescein-tagged streptavidin (1:500 dilution) or Alexa Fluor 488-conjugated secondary antibodies (Ig, heavy and light chains; 1:1,000 dilution; Life Technologies) in 10% normal donkey serum. This secondary incubation was done for 1 hour at 25°C. Slides were washed 3 times in PBS, and coverslips were mounted to the slides with Prolong Gold containing DAPI (Life Technologies). Oculdin and E-cadherin sections were subject to antigen retrieval with boiling in sodium citrate buffer (10 mM, pH 6) for 30 minutes prior to blocking. TUNEL staining for apoptotic cells was done using paraffin sections (5 μm thick) according to the protocol supplied with the Promega DeadEnd Fluorometric TUNEL System (Promega). Apoptotic cells were labeled with fluorescein, and sections were counterstained with propidium iodide. Images were obtained using a Leica TCS-SP laser scanning confocal microscope (Leica). Image software was used to generate individual images. Paraffin processing, embedding, sectioning, and histological staining with alcin blue (pH 2.5) and Masson trichrome were performed as described previously (33). For alcin blue staining, tissues were fixed in Carnoy’s fixative (60% ethanol, 30% chloroform, and 10% glacial acetic acid) before paraffin embedding to preserve mucus.

Transmission electron microscopy (TEM). Mice were perfused with 1% glutaraldehyde and 2% paraformaldehyde fixative in 0.1 M phosphate buffer. Cervical and uterine tissue was removed and fixed in 2.5% glutaraldehyde in 0.1 M cacodylate buffer containing 0.1% ruthenium red overnight at 4°C. Tissue was then cut into 250-μm

Figure 6. HA depletion compromises epithelial barrier function and increases susceptibility to infection-mediated PTB. Gene expression of classical (Ptgs2, Il1a, and Tnfa) and alternative (Ym1 and Arg) immune response after 24-hour live vaginal E. coli exposure (10^6 CFU) in WT and Has1/2/3 KO (KO) mice. n = 4 per group. *P < 0.05 vs. uninfected, 1-way ANOVA with pairwise multiple comparisons by Tukey test.
Figure 7. HA depletion compromises epithelial and mucosal barrier functions. (A) siRNA-mediated Has3 silencing increased permeability of confluent ECT-1 cells. However, treatment with exogenous HA did not restore siRNA-treated cells to control levels. FACE analysis confirmed 60%–70% HA knockdown in Has3 siRNA-treated groups. (B) Fluorescent PSPEGs (red) penetrated deeper into the mucus layer in Has1/2/3 KO mice than in WT controls. TFF1 staining (green) marks mucus and mucosal epithelia. Nuclei were stained with DAPI (blue). n = 4–5 per group. *P < 0.05, 1-way ANOVA with pairwise multiple comparisons by Tukey test. Scale bars: 50 μm.
RNA/20 μl volume iScript Reverse Transcription Supermix (Bio-Rad). Quantitative real-time PCR was performed using SYBR Green and a PRISM 7900HT Sequence Detection System (Applied Biosystems). Aliquots (20 ng) of cDNA were used for each reaction and were run in triplicate. Each gene was normalized to the expression of the housekeeping genes cyclophilin (mouse) or 36B4 (human). Gene expression was calculated according to the 2^(-ΔΔCt) method, as described by the manufacturer (user bulletin no. 2; Applied Biosystems). The panel of cell junction genes in cervixes (Supplemental Table 3) was assayed using the RT^2 Profiler PCR Array Mouse Cell Junction Pathway Finder Kit (Qiagen) according to the manufacturer’s instructions.

**Statistics.** Data were analyzed using 1-way ANOVA with pairwise multiple comparisons performed with Tukey test for data normally distributed. Data are displayed as mean ± SEM. Differences in PTB rates between genotypes (Table 2 and Supplemental Figure 4) were analyzed using Fisher exact test. A P value less than 0.05 was considered statistically significant.

**Study approval.** All animal studies were conducted in accordance with the standards of humane animal care as described in the NIH Guide for the Care and Use of Laboratory Animals. The research protocols were approved by the IACUC office at University of Texas Southwestern Medical Center. Because human cells used in this study were an immortalized cell line from normal cervical epithelia purchased from ATCC, human subject approval and informed consent were not required.
