Immune activation caused by vascular oxidation promotes fibrosis and hypertension

Jing Wu, … , Meena S. Madhur, David G. Harrison

Vascular oxidative injury accompanies many common conditions associated with hypertension. In the present study, we employed mouse models with excessive vascular production of ROS (tg\textsuperscript{sm/p22phox} mice, which overexpress the NADPH oxidase subunit p22\textsuperscript{phox} in smooth muscle, and mice with vascular-specific deletion of extracellular SOD) and have shown that these animals develop vascular collagen deposition, aortic stiffening, renal dysfunction, and hypertension with age. T cells from tg\textsuperscript{sm/p22phox} mice produced high levels of IL-17A and IFN-\gamma. Crossing tg\textsuperscript{sm/p22phox} mice with lymphocyte-deficient \textit{Rag1}\textsuperscript{−/−} mice eliminated vascular inflammation, aortic stiffening, renal dysfunction, and hypertension; however, adoptive transfer of T cells restored these processes. Isoketal-protein adducts, which are immunogenic, were increased in aortas, DCs, and macrophages of tg\textsuperscript{sm/p22phox} mice. Autologous pulsing with tg\textsuperscript{sm/p22phox} aortic homogenates promoted DCs of tg\textsuperscript{sm/p22phox} mice to stimulate T cell proliferation and production of IFN-\gamma, IL-17A, and TNF-\alpha. Treatment with the superoxide scavenger tempol or the isoketal scavenger 2-hydroxybenzylamine (2-HOBA) normalized blood pressure; prevented vascular inflammation, aortic stiffening, and hypertension; and prevented DC and T cell activation. Moreover, in human aortas, the aortic content of isoketal adducts correlated with fibrosis and inflammation severity. Together, these results define a pathway linking vascular [...]

Vascular oxidative injury accompanies many common conditions associated with hypertension. In the present study, we employed mouse models with excessive vascular production of ROS (tgsm/p22phox mice, which overexpress the NADPH oxidase subunit p22phox in smooth muscle, and mice with vascular-specific deletion of extracellular SOD) and have shown that these animals develop vascular collagen deposition, aortic stiffening, renal dysfunction, and hypertension with age. T cells from tgsm/p22phox mice produced high levels of IL-17A and IFN-γ. Crossing tgsm/p22phox mice with lymphocyte-deficient Rag1–/– mice eliminated vascular inflammation, aortic stiffening, renal dysfunction, and hypertension; however, adoptive transfer of T cells restored these processes. Isoketal-protein adducts, which are immunogenic, were increased in aortas, DCs, and macrophages of tgsm/p22phox mice. Autologous pulsing with tgsm/p22phox aortic homogenates promoted DCs of tgsm/p22phox mice to stimulate T cell proliferation and production of IFN-γ, IL-17A, and TNF-α. Treatment with the superoxide scavenger tempol or the isoketal scavenger 2-hydroxybenzylamine (2-HOBA) normalized blood pressure; prevented vascular inflammation, aortic stiffening, and hypertension; and prevented DC and T cell activation. Moreover, in human aortas, the aortic content of isoketal adducts correlated with fibrosis and inflammation severity. Together, these results define a pathway linking vascular oxidant stress to immune activation and aortic stiffening and provide insight into the systemic inflammation encountered in common vascular diseases.

Introduction

The normal aorta expands to accommodate a portion of the ejected blood during cardiac contraction and then recoils during cardiac relaxation. This capacitance, or Windkessel function, of the aorta reduces systolic pressure and maintains pressure and peripheral perfusion during diastole. In several conditions—including aging, autoimmune diseases, cigarette smoking, diabetes, obesity, and hypertension—the aorta stiffens, leading to loss of the Windkessel function and systolic hypertension. Pulse wave velocity (PWV), a surrogate measure of aortic stiffness, predicts untoward outcomes in aged and hypertensive humans (1, 2). A recent analysis of the Framingham population indicates that aortic stiffening precedes hypertension and that higher forward pressure wave amplitude, a hallmark of aortic stiffening, is associated with increased risk for incident cardiovascular diseases (3, 4).

A common feature of many conditions associated with aortic stiffening is vascular oxidant stress. Clinically, plasma levels of myeloperoxidase and F2-isoprostanes correlate with arterial stiffening in humans (5). Studies in experimental animals have implicated ROS in fibrotic changes in blood vessels, lungs, skin, and other tissues (6, 7). In addition to oxidative events, chronic inflammation is associated with arterial stiffness in humans (8–10). Patients with systemic lupus erythematosus, rheumatoid arthritis, and psoriasis exhibit increased aortic stiffness, and TNF-α antagonists improve parameters of aortic stiffness in patients with rheumatoid arthritis (11, 12). We have shown that hypertension is associated with the infiltration of immune cells into the adventitia and periadventitial fat, as well as the activation of T cells that release proinflammatory cytokines such as IL-17A, IFN-γ, and TNF-α (13, 14). IL-17A induces collagen synthesis in fibroblasts via activation of p38 MAP kinase (15). IFN-γ also promotes hypertension-related fibrosis in the heart, arteries, and the kidney (16).

A potential mechanism linking oxidative injury to immune activation and inflammation relates to modification of self-proteins. In particular, isoketals—alternatively referred to as isolevuglandins or γ-ketoaldehydes—are formed from fatty acid oxidation and react with protein lysines to form oxidized pyrrole adducts. These modified proteins become auto-antigens and can elicit antibody formation (17). We have recently shown that hypertension is associated with accumulation of isoketal-adducted...
tein adducts, vascular inflammation, aortic stiffening, renal dysfunction, and hypertension. These experiments provide new insight into how diverse conditions diminish aortic compliance, alter renal function, and ultimately cause hypertension. These findings also show how vascular diseases associated with vascular oxidative injury can lead to systemic immune activation and inflammation.

Results

Chronic vascular oxidative stress induces aortic stiffening and hypertension. As an initial approach to determine if vascular oxidative stress promotes aortic stiffening, we studied tg<sup>em/p22phox</sup> mice. These animals have smooth muscle-targeted overexpression of p22<sup>phox</sup>, a docking subunit of all murine NADPH oxidase catalytic subunits (19). Vessels from these mice exhibit increased vascular

Figure 1. Tg<sup>em/p22phox</sup> mice develop age-related aortic stiffening and hypertension. (A) Effects of aging on vascular collagen deposition in WT and Tg<sup>em/p22phox</sup> mice. Perfusion-fixed sections of the thoracic aortas were sectioned (6 μm) and stained with Masson’s trichrome to highlight collagen (blue). Areas within the red boxes were magnified (×20) and shown below the original images (×6). Scale bars: 100 μm. (B) Adventitial collagen area was quantified by planimetry. *P < 0.05 vs. WT; **P < 0.01 vs. 3 months. (C) Aortic collagen quantification by hydroxyproline assay. (D and E) Freshly isolated aortas were mounted on a myograph system in Ca<sup>2+</sup>-free buffer to determine pressure-diameter relationships. Stress-strain relationships were constructed from intraluminal pressure, wall thickness, and inner and outer diameters. These parameters were measured at 25 mmHg step changes in pressure from 0–200 mmHg. **P < 0.01 vs. Tg 3 months; ***P < 0.01 vs. WT. (F and G) Telemetry blood pressure of WT and Tg<sup>em/p22phox</sup> mice at 3, 6, and 9 months of age. †P < 0.05 vs. Tg 6 months; ††P <0.01 vs. Tg 6 months. Data were analyzed using 2-way ANOVA; n = 6–9.
Nox1 expression and a 2-fold increase in vascular superoxide and hydrogen peroxide production (19). Masson’s trichrome staining revealed minimal collagen staining in the aorta of WT mice at either 3, 6, or 9 months of age (Figure 1, A and B). In contrast, aortic adventitial collagen content was increased in the tgsm/p22phox mice at 6 and 9 months of age. Hydroxyproline analysis confirmed that aortic collagen content was increased by about 2-fold at 6 and 9 months of age in tgsm/p22phox mice (Figure 1C).

Mechanical properties of the aortas of WT and tgsm/p22phox mice were studied ex vivo in a pressurized vessel apparatus. Aortas from WT mice at 3, 6, and 9 months of age demonstrated identical increases in diameter as intraluminal pressure was increased (Figure 1D). Aortas from 3-month-old tgsm/p22phox mice were similar to those of WT mice, but at 6 and 9 months of age, aortas from these mice demonstrated depressed pressure-diameter relationships. This was reflected by a leftward shift in the stress-strain curves (Figure 1E), indicating increased stiffness of the aortas of tgsm/p22phox mice at 6 and 9 months of age.

To confirm aortic stiffening in vivo, we measured PWV as previously described (20). At 3 months of age, PWV in WT and tgsm/p22phox mice was similar; however, with aging, this parameter increased in tgsm/p22phox mice but did not significantly change in WT mice (Supplemental Figure 1; supplemental material available online with this article; doi:10.1172/JCI80761DS1).

Figure 2. Vascular oxidative stress induced by deletion of smooth muscle Sod3 promotes age-related aortic stiffening and hypertension. (A) Masson’s trichrome blue staining in 3-, 6-, and 9-month-old Sod3fl/fl Cre– and Sod3fl/fl Smmhc-Cre mice. Tamoxifen was administered at 3 mg/20 kg in corn oil via i.p. injection at 10 weeks of age. Images are ×20 magnification. Scale bars: 100 μm. (B) Aortic hydroxyproline content. (C and D) Pressure diameter relationship and stress-strain relationships. (E and F) Blood pressure measured by radiotelemetry (n = 6–8). #P < 0.05 vs. Cre–/–; *P < 0.05 vs. Sod3fl/fl Smmhc-Cre 3 month; **P < 0.05 vs. Sod3fl/fl Smmhc-Cre 3 month. Aortic hydroxyproline content was analyzed using 2-way ANOVA. Pressure diameter relationships, stress-strain relationships, and blood pressures were analyzed using 1-way ANOVA with repeated measures.
Although aortic stiffening developed at 6 months of age in \( \text{tg}^{\text{m}/\text{p22phox}} \) mice, their blood pressure remained normal at this time. At 9 months of age, however, \( \text{tg}^{\text{m}/\text{p22phox}} \) mice developed moderate hypertension, while WT mice remained normotensive (Figure 1, F and G). Analysis of heart rate variability showed an increase in the low-frequency to high-frequency ratio (LF/HF) in both WT and \( \text{tg}^{\text{m}/\text{p22phox}} \) mice at 6 and 9 months of age, but this was not different between the genotypes (Supplemental Figure 2). Thus, in \( \text{tg}^{\text{m}/\text{p22phox}} \) mice, aortic stiffening precedes blood pressure elevation, mimicking the sequence of these events in humans. This increase in blood pressure does not seem to be related to increased sympathetic outflow.

The effects of oxidative stress on aortic stiffening and age-related hypertension were confirmed in mice with vascular smooth muscle–targeted deletion of the extracellular SOD (\( \text{Sod3}^{\text{fl/fl}} \text{Smmhc-Cre} \) mice, another model of vascular oxidative stress (21). Deletion of \( \text{Sod3} \) was induced at 10 weeks of age by injection of tamoxifen. As controls, \( \text{Sod3}^{\text{fl/fl}} \) mice lacking Cre recombinase were also treated with tamoxifen. At 3 months of age, shortly after \( \text{Sod3} \) deletion, there was no significant difference in aortic collagen between these 2 groups of animals, as estimated by Masson’s trichrome staining or quantified by hydroxyproline content (Figure 2, A and B). By 6 months of age, mice with \( \text{Sod3} \) deletion had a marked increase in adventitial collagen compared with \( \text{Sod3}^{\text{fl/fl}} \) mice lacking Cre recombinase. This was associated with development of aortic stiffening (Figure 2, C and D) but no increase in blood pressure (Figure 2, E and F). By 9 months of age, the SOD3-deficient mice exhibited not only aortic stiffening, but also a significant elevation of blood pressure (Figure 2, A–F). Collectively, these data recapitulate our finding in \( \text{tg}^{\text{m}/\text{p22phox}} \) mice and support a role of vascular ROS in promoting vascular fibrosis, aortic stiffening, and age-related hypertension.

Oxidative stress–induced vascular inflammation contributes to age-related hypertension. We and others have previously demonstrated that vascular inflammation contributes to the development of hypertension and aortic stiffening (13–16, 22). We therefore sought to determine if chronic oxidative stress promotes vascular inflammation in \( \text{tg}^{\text{m}/\text{p22phox}} \) mice. Flow cytometry of single cell suspensions revealed that total leukocytes, monocyte/macrophages, B cells, total T cells, and CD4+ and CD8+ T cell subsets were all increased in aortas of 6- and 9-month-old \( \text{tg}^{\text{m}/\text{p22phox}} \) mice compared with similarly aged WT mice (Figure 3, A–N). IHC using anti-CD3 indicated that T lymphocytes were predominantly...
located in the adventitia and perivascular fat of thoracic aortas in Tgsm/p22phox mice at 6 and 9 months of age, compared withagematched WT mice (Supplemental Figure 3).

In additional experiments, we examined the production of cytokines by aortic T cells using intracellular staining. At 3 months of age, the few T cells in the aorta of Tgsm/p22phox mice produced minimal amounts of IFN-γ, IL-17A, or TNF-α; however, by 6 and 9 months, the number of both CD8+ and CD4+ T cells in the aorta producing these cytokines was significantly increased (Figure 4, A–G).

Chronic vascular oxidative stress promotes age-related renal inflammation, fibrosis, and dysfunction. We considered the hypothesis that chronic vascular oxidative stress might predispose to renal inflammation and dysfunction. Flow cytometry of kidney single cell suspensions showed a significant increase in total leukocytes, monocyte/macrophages, DCs, total T cells, and both CD4+ and CD8+ T cells at 9 months of age but not at earlier time points in Tgsm/p22phox mice (Figure 5, A–G). IHC showed that CD3+ cells accumulate in the periglomerular and perivascular regions of 9-month-old Tgsm/p22phox mice. In contrast, there was minimal accumulation of immune cells, as assessed by either flow cytometry or IHC in aged WT mice (Figure 6A). In parallel with T cell infiltration, Masson’s trichrome staining revealed perivascular collagen deposition in the kidney of 9-month-old Tgsm/p22phox mice but not WT mice (Figure 6B). These changes in renal inflammation and fibrosis were paralleled by a decline in the capacity of mice to excrete a volume and sodium challenge. Mice received an i.p. injection of normal saline equal to 10% of their body weight, and the urine volume and sodium excreted in the subsequent 4 hours was monitored as previously described (23, 24). This analysis revealed that Tgsm/p22phox mice exhibited an accelerated decline in their ability to excrete this volume and sodium load with aging (Figure 6, C and D). Thus, chronic vascular oxidative stress initially causes vascular inflammation and subsequent renal inflammation, fibrosis, and dysfunction. These perturbations of renal function temporally correspond to the elevation of blood pressure observed in these mice.

T lymphocytes are required for collagen deposition, aortic stiffening, and hypertension in mice with chronic vascular oxidative stress. Because T cells contribute to hypertension in other models, we crossed Tgsm/p22phox mice with mice lacking the Rag-1−/− mice, to generate Tgsm/p22phox × Rag-1−/− mice. Unlike Tgsm/p22phox mice, Tgsm/p22phox × Rag-1−/− mice did not develop collagen deposition (Figure 7, A–C), aortic stiffening (Figure 7, D and E), or hypertension (Figure 7, F...
To further examine a role of T cells in aortic stiffening and hypertension in response to vascular oxidative stress, we adoptively transferred $2 \times 10^7$ T cells to $tg^{sm/p22phox} \times Rag-1^{-/-}$ mice at 3 months of age and allowed them to survive until 9 months of age. Adoptive transfer of T cells restored collagen deposition, aortic stiffening, and blood pressure elevation in the $tg^{sm/p22phox} \times Rag-1^{-/-}$ mice, supporting an essential role of T cells in the development of aortic fibrosis and hypertension induced by chronic vascular oxidative stress. Likewise, deficiency of $Rag-1$ protected mice from a decline in their ability to excrete a sodium and volume load at 9 months of age, while this protection was lost in mice that had undergone adoptive transfer of T cells (Supplemental Figure 4).

Isoketals accumulate in the aorta and antigen presenting cells of $tg^{sm/p22phox}$ mice. Because pyrrole-modified proteins can act as autoantigens and stimulate inflammatory responses (17, 18), we sought to determine if chronic vascular oxidant stress promotes their formation. We used stable isotope dilution liquid chromatography/mass spectrometry (LC/MS) analysis of isoketal-lysyl-lactam to quantify isoketal-protein adducts in thoracic aortic homogenates of 9-month-old mice (Figure 8A, red arrows). Aortic isoketal-protein adducts were markedly elevated in $tg^{sm/p22phox}$ mice compared with WT mice (Figure 8B). Flow cytometry of single cell suspensions confirmed a higher content of isoketal adducts in CD45+ cells of the $tg^{sm/p22phox}$ aortas compared with aortas of WT mice at 3, 6, and 9 months of age. These tended to increase in the transgenic mice, but this did not reach statistical significance (Supplemental Figure 5).

To further confirm the presence of isoketal-protein adducts in vessels of $tg^{sm/p22phox}$ mice, we performed immunohistochemical staining using the single chain antibody D11 (18). Abundant isoketal-protein adducts were identified in aortas of 9-month-old $tg^{sm/p22phox}$ mice but not WT mice (Figure 8C). Treatment of mice from 4–9 months of age with either the SOD mimetic tempol or the isoketal scavenging agent 2-hydroxybenzylamine (2-HOBA) eliminated isoketal staining in the $tg^{sm/p22phox}$ mouse vessels.

In additional experiments, we found that isoketals also accumulate in antigen presenting cells (APCs) of $tg^{sm/p22phox}$ mice. Using a recently described gating strategy (25), macrophages were identified as CD64+MerTK+, and DCs were selected from the remaining cells as CD11c+ and MHC-II+ cells (Supplemental Figure 6). Monocytes were identified as CD11b+CD64+F4/80+SSClo cells. Virtually all monocytes were Ly-6C+, and most expressed MHC-II. Intracellular staining for isoketals using D11 conjugated to Alexa Fluor 488 revealed that DCs, macrophages, and to a smaller extent monocytes of 9-month-old $tg^{sm/p22phox}$ mice accumulate isoketal-protein adducts, while cells of age-matched WT animals do not (Figure 8, D–I). This was prevented by chronic treatment with either tempol or 2-HOBA.

We also analyzed the presence of isoketal adducts in peptides eluted from MHC-I using a dot blot analysis and the D11 antibody. Peptides from 9-month-old WT mice were devoid of such adducts; however, those eluted from DCs of aged $tg^{sm/p22phox}$ mice were clearly modified by isoketals (Figure 8J). Thus, DCs from mice with chronic vascular oxidative stress present oxidatively modified peptides.
Scavenging of ROS prevents vascular inflammation, aortic stiffening, renal dysfunction, and hypertension in \( \text{tg}^{\text{emo/p22phox}} \) mice. To determine if scavenging superoxide or isoketals prevents vascular oxidative stress–induced aortic stiffening and hypertension, we treated mice with either tempol or 2-HOBA from 4–9 months of age and monitored blood pressure with telemetry. Both of these therapies prevented aortic fibrosis in \( \text{tg}^{\text{emo/p22phox}} \) mice at 6 and 9 months of age (Figure 9, A–C). Similarly, treatment with either tempol or 2-HOBA prevented aortic stiffening and age-related hypertension (Figure 9, D–G). Treatment with either tempol or 2-HOBA also preserved the ability to excrete a sodium and volume challenge at 9 months of age (Supplemental Figure 7). These data support a role of vascular ROS in promoting vascular fibrosis, aortic stiffening, and age-related hypertension. Despite the effectiveness of tempol and 2-HOBA in preventing aortic stiffening and hypertension, we found that these agents did not reverse these abnormalities if introduced at 7 months of age (Supplemental Figure 8).

To determine if superoxide or isoketal scavenging reduced vascular inflammation, we performed flow cytometry on the aortas of \( \text{tg}^{\text{emo/p22phox}} \) mice treated with vehicle, tempol, or 2-HOBA from 4–9 months of age. Both tempol and 2-HOBA markedly reduced the aortic infiltration of leukocytes (Figure 10, A–C). The infiltrating CD45+ total leukocytes, F4/80+ monocyte/macrophages, CD19+ B cells, CD3+ total T cells, and CD4+ and CD8+ T cell subsets were significantly reduced by either of these treatments (Figure 10, D–I).

Vascular oxidative stress promotes cytokine production by splenic T cells. We and others have previously shown that IL-17A and IFN-γ contribute to hypertension (14, 16, 26) and that IL-17A plays a critical role in aortic stiffening (15). We therefore sought to determine if T cells of mice with vascular oxidative stress produce IL-17A and IFN-γ. Splenic T cells from 9-month-old WT and \( \text{tg}^{\text{emo/p22phox}} \) mice were analyzed by flow cytometry using intracellular staining for these cytokines (Figure 11A). While WT T cells produced minimal amounts of IL-17A, 5% of CD4+ T cells and 10% of double-negative (CD3−/CD4−/CD8−) T cells of \( \text{tg}^{\text{emo/p22phox}} \) mice produced this cytokine (Figure 11, B and D–F). Likewise, IFN-γ–producing cells were doubled in all 3 subsets of T lymphocytes in \( \text{tg}^{\text{emo/p22phox}} \) mice compared with WT (Figure 11, C and G–I). Treatment with tempol or 2-HOBA normalized T cell production of IL-17A and IFN-γ in \( \text{tg}^{\text{emo/p22phox}} \) mice. These data suggest that vascular oxidative stress systemically activates T cells and promotes their proinflammatory cytokine production.

Protein homogenates of \( \text{tg}^{\text{emo/p22phox}} \) mouse vessels are immunogenic. We have shown that isoketal-protein adducts promote maturation and activation of DCs in angiotensin II–induced hypertension and that these activated DCs can drive proliferation of T cells from angiotensin II–treated mice (18). To determine if proteins from the aortas of \( \text{tg}^{\text{emo/p22phox}} \) mice are immunogenic, we prepared aortic homogenates from WT and \( \text{tg}^{\text{emo/p22phox}} \) mice at 9 months of age. These were used to pulse naive DCs from WT mice for 2 hours and were then washed from the cells (Figure 12A). The pulsed DCs were then cocultured with \( 1 \times 10^7 \) T cells isolated from the spleen of either WT or \( \text{tg}^{\text{emo/p22phox}} \) mice and prelabeled with CFSE at a ratio of 1:10. Of note, T cells isolated from \( \text{tg}^{\text{emo/p22phox}} \) mice, but not those from WT mice, survived and proliferated in response to the stimulation of immunogenic protein homogenate of \( \text{tg}^{\text{emo/p22phox}} \) mice, suggesting that preexposure to isoketal-adducted antigens in vivo
primed these cells for clonal expansion upon a second challenge (Figure 12, B–I). Aortic homogenates of tgsm/p22phox mice, but not WT mice, supported survival of CD3+ (Figure 12, B and F), CD4+, and CD8+ T cells (Figure 12, C and G) when presented to T cells by DCs. DCs pulsed with tgsm/p22phox aortic homogenates also induced proliferation of CD4+ (Figure 12, D and H) and to a lesser extent CD8+ T cells (Figure 12, E and I), and increased the release of IL-17A/F, IFN-γ, and TNF-α into the medium (Table 1). Chronic treatment of tgsm/p22phox mice with tempol or 2-HOBA reduced the immunogenicity of their aortic protein, as indicated by the diminished survival, proliferation, and cytokine production of T cells in this assay.

To determine if DCs were functionally activated in these conditions, we also evaluated the polarizing cytokines released into the medium. When DCs exposed to tgsm/p22phox aortic homogenates were cocultured with T cells isolated from tgsm/p22phox mice, there was a marked increase of GM-CSF, IL-1α, IL-1β, IL-6, TGF-β1, and TGF-β3 (Table 1). These increases were blunted when DCs were primed with aortic homogenates from tgsm/p22phox mice chronically
Figure 8. Chronic vascular oxidative stress promotes isoketal-adduct formation. Representative LC/MS chromatograms from pooled samples for each group (A). The left panel shows chromatograms for IsoK-Lys in samples, while the right panel shows chromatograms for [13C6,15N2] internal standards in the same samples. Mann-Whitney tests were employed for analysis. The bar graph in B shows mean data. (C) Fix-perfused mouse aortas were embedded in paraffin and subjected to IHC for isoketal staining. Images are ×20 magnification. Scale bars: 100 μm. (D–I) Intracellular staining for isoketals in spleen macrophages (D and E), DCs (F and G), and monocytes (H and I). These data were analyzed using 1-way ANOVA, n = 6. *P < 0.05; **P < 0.01. (J) DCs isolated from 9-month-old WT and Tgemplp22phox mice were exposed to weak acid to elute peptides presented on MHC-I complexes. The presence of isoketal-adducted peptides in the eluent was visualized by dot blot. Isoketal adducts were present in 3 of 4 Tgemplp22phox mice but not in WT mice (see Supplemental Figure 5C for full uncut gel).
treated with tempol or 2-HOBA, suggesting that superoxide and isoketals contribute to immunogenicity of vascular proteins. Interestingly, tg^{mip22phox} mouse aortic homogenates failed to induce DCs to produce these cytokines if they were cocultured with T cells from WT mice, suggesting that interactions with isoketal-primed T cells also promote DC activation. Other cytokines — such as IL-2, IL-12 (p40), IL-12 (p70), IL-21, IL-23, and TGF-β2 — were either undetectable or not differentially produced across treatment groups.

Evidence that the isoprostane/isoketal pathway contributes to aortic stiffening and inflammation in humans. To determine if our findings in mice have relevance to humans, we performed 2 additional studies. First, we examined the degree of fibrosis and the presence of isoketal adducts and T cells in sections of human aortas using staining with Masson’s trichrome, D11, and anti-CD3, respectively. Unlike mouse vessels, human aortas were often noted to contain collagen and T cells not only in the adventitia, but also in the media (Figure 13A). Despite this difference in species, we found that the severity of fibrosis was significantly correlated with the presence of isoketal adducts (Figure 13, A and B) and T cells (Figure 13, A and C) in human aortas. Additionally, there was also correlation between the presence of T cells and isoketal adducts (Figure 13, A and D).
Our present study defines a new pathway in which vascular oxidative stress promotes systemic inflammation via formation of immunogenic isoketal-protein adducts. These act as autoantigens that are presented to T lymphocytes by APCs, leading to T cell activation. These activated T cells then infiltrate the vascular adventitia and release cytokines that induce collagen deposition, leading to aortic stiffening, renal inflammation and dysfunction, and ultimately hypertension (Figure 14). Aortic stiffening accompanies several common conditions, including aging, hypertension, atherosclerosis, overt diabetes, obesity, and cigarette smoking (5, 27–29). In many of these conditions, vascular oxidative stress is known to exist and might initiate the pathway delineated in this study.

A recent analysis of the Framingham population indicates that aortic stiffening precedes development of overt hypertension (3). In this regard, the Tg^{mip22phox} mouse recapitulates this sequence of events. At 6 months, aortic compliance is reduced in these ani-
Figure 11. Cytokine production of T cells in the spleen of mice with chronic vascular oxidative stress. (A) Gating strategy for identifying T cell populations among total spleenocytes. (B–I) Intracellular staining indicating IL-17A (B, D–F) and IFN-γ (C, G–I) production in T cell subsets in WT and Tg^emos^ mice. Bar graphs were analyzed using 1-way ANOVA (n = 5–7). **P < 0.01.
increased PWV and higher forward pressure wave amplitude, contribute separately to the risk of adverse cardiovascular outcomes (3, 4). Of note, PWV is elevated in tgsm/p22phox mice at 6 months of age, prior to the development of renal inflammation, fibrosis, and dysfunction, supporting the notion that aortic stiffening directly causes renal damage and, ultimately, hypertension. Taken

(B, C, F, and G) Flow cytometry and bar graphs identifying live CD3+ T cells and CD4+CD8- T cell subsets from cocultured DCs and T cells. (D, E, H, and I) Representative flow cytometry images and bar graphs showing percentages and numbers of proliferating CD4+ (D and H) and CD8+ (E and I) T cells, as determined using CSFE dilution (n = 6, 1-way ANOVA). Homo, homogenates. Black lines indicate original data, orange peaks indicate initial population, and purple peaks indicate generations of cells undergoing division as simulated by FlowJo 7.6.4 software. *P < 0.05 compared with Tgsm/p22phox homogenate + Tgsm/p22phox T cells; **P < 0.01 Tgsm/p22phox homogenate + Tgsm/p22phox T cells.

...mals prior to development of hypertension. At 9 months, these mice develop modest elevations of blood pressure, while WT mice remain normotensive at this age. We also observed identical chronological changes in aortic stiffening and hypertension in mice with targeted vascular smooth muscle deletion of Sod3. Hemodynamic changes caused by aortic stiffening, including
from tgsm/p22phox mice markedly activate T cells from this same genotype by splenic T cells. Moreover, DCs primed with aortic homogenates organ damage in hypertension (13–16, 30). In the present study, we derived cytokines in the development of tissue fibrosis and target oxidative stress might contribute to the human disease. vascular oxidative stress recapitulate age-related aortic stiffening together, data from these 2 models suggest that mice with chronic vascular oxidative stress recapitulate age-related aortic stiffening and hypertension in humans and suggest that chronic vascular oxidative stress might contribute to the human disease. Studies by our laboratory and others have implicated T cell-derived cytokines in the development of tissue fibrosis and target organ damage in hypertension (13–16, 30). In the present study, we found that vascular oxidative stress induces production of IL-17A by splenic T cells. Moreover, DCs primed with aortic homogenates from tgsm/p22phox mice markedly activate T cells from this same genotype but not T cells from WT mice. This activation profile included not only proliferation, but also robust production of IL-17A, IL-17F, IL-23, IL-21, and GM-CSF — by DCs primed with tgsm/p22phox aorta homogenates and Tgsm/p22phox T cells. This suggests that not only do DCs stimulate T cell proliferation and cytokine production, but also that T cells with T cell receptors that respond to isoketal adducts reciprocally activate DCs. One such signal might involve costimulatory engagement of DC B7 ligands by T cell CD28, which we have previously shown to be critical for hypertension and T cell activation in this disease (32). In this regard, Orabona et al. have shown that CD28 can stimulate DCs to produce IL-6, IFN-γ, and to a lesser extent IL-23 in a B7 and p38 MAP kinase–dependent fashion (33).

Macrophages and monocytes can also function as APCs and have the capability to trigger adaptive immune responses in addition to professional DCs (25). In the present study, we found an increase of total F4/80+ cells in the aorta of Tgsm/p22phox mice with aging. In addition, we found that splenic macrophages and monocytes of Tgsm/p22phox mice accumulate isoketal adducts. We have previously shown that monocyte/macrophage-like cells do not increase expression of the B7 ligands, CD80 and CD86, by T cell CD28, which we have previously shown to be critical for T cell activation (18). Instead, data from these 2 models suggest that mice with chronic vascular oxidative stress recapitulate age-related aortic stiffening and hypertension in humans and suggest that chronic vascular oxidative stress might contribute to the human disease.

Studies by our laboratory and others have implicated T cell-derived cytokines in the development of tissue fibrosis and target organ damage in hypertension (13–16, 30). In the present study, we found that vascular oxidative stress induces production of IL-17A by splenic T cells. Moreover, DCs primed with aortic homogenates from tgsm/p22phox mice markedly activate T cells from this same genotype but not T cells from WT mice. This activation profile included not only proliferation, but also robust production of IL-17A, IL-17F, IL-23, IL-21, and GM-CSF — by DCs primed with tgsm/p22phox aorta homogenates and Tgsm/p22phox T cells.

Related to the above considerations, a striking finding in the current study is the marked production of cytokines — including IL-1β, IL-6, TGF-β1, and GM-CSF — by DCs primed with tgsm/p22phox aortic homogenates when exposed to T cells from Tgsm/p22phox mice.

*P < 0.05, *P < 0.01 vs. the combination of Tgsm/p22phox aorta homogenate and Tgsm/p22phox T cells.
Age were implanted with telemetry units. Ten days later, blood pressure was recorded for 10 minutes every hour for 3 days. In additional \( \text{tg}^{\text{m/p22phox}} \) mice, tempol \( (n = 6) \) or 2-HOBA \( (n = 6) \) was administered in the drinking water from 4–9 months of age. In some experiments, 3-month-old \( \text{tg}^{\text{m/p22phox}} \times \text{Rag-1}^{–/–} \) mice underwent adoptive transfer of T cells as described previously \((13, 15, 32)\). Nine-month-old \( \text{tg} \text{sm/p22phox} \times \text{Rag-1}^{–/–} \) mice, with or without T cell reconstitution, were used for blood pressure and vascular stiffness measurements. \( \text{Sod3}^{fl/fl} \) \text{Smmhc-Cre} \) mice and \( \text{Sod3}^{fl/fl} \times \text{Cre}^{–} \) mice were treated with tamoxifen (3 mg/20 kg, dissolved in corn oil) via 5 consecutive i.p. injections at 10 weeks of age and were studied at 9 months of age \((21)\).

**Power spectral analysis of heart rate variability.** Blood pressure was recorded by telemetry for 5 minutes every hour at a sampling rate of 500 Hz, and data were extracted from waveform pressure. Heart rate variability was analyzed from multiple artifact-free blood pressure records of each mouse by LabChart Pro software \((ADInstruments)\). Power spectra were calculated as previously described \((21)\).

**Ex vivo measurement of aortic stiffness.** For studies of vascular stiffness, the descending thoracic aorta was mounted on cannulas at the in situ length in calcium-free buffer \((44)\). Intraluminal pressure was increased in a step-wise fashion while video microscopy was used to follow wall thickness and vessel diameter. Diameters were recorded at increments of 25 mmHg from 0–200 mmHg. Stress-strain relationships were calculated as described by Baumbach et al. \((44)\). Hydroxyproline was measured in isolated thoracic aortas as previously described \((45–47)\).

**In vivo measurement of PWV.** PWV was measured using the transit time method with Doppler ultrasound \((\text{Vevo} 2100,\ \text{VisualSonics})\) as previously described \((20)\). Briefly, mice were anesthetized with 2% isoflurane/air and maintained under light anesthesia. Mice were kept at supine positions on a heated platform (38°C) with ECG electrodes taped to their paws for continuous recordings. Thoracic and abdominal hair was removed. Pressure waveforms were imaged 1 mm below the exit to the left subclavian artery and 1 mm above the exit to left renal artery on the descending aorta. Arrival times were calculated based on the distances between the foot of the pressure waveform and the peak of R wave for both the proximal and distal locations \((\text{Supplemental Figure 1B})\). The transit time was calculated as the difference in these arrival times and was averaged over 5 cardiac cycles. The in situ distances between these 2 positions were measured postmortem with a ruler. PWV \((\text{m/s})\) was calculated by dividing the distance by the transit time.

**Flow cytometry.** Single cell suspensions were prepared from aortas as previously described \((15, 32)\). Briefly, the entire aorta with surrounding perivascular fat was minced with fine scissors and digested with 1 mg/ml collagenase A, 1 mg/ml collagenase B, and 100 μg/ml DNAase I in phenol-free RPMI 1640 medium with 5% FBS for 30 minutes at 37°C, with intermittent agitation. Fc receptors were blocked with CD16/CD32 for 20 minutes at 4°C \((\text{clone} \ 2.4G2,\ \text{BD Biosciences})\) prior

---

**Figure 13. Role of isoketal and oxidation in aortic collagen deposition and stiffening in humans.** (A–D) Data from human aortas. (E) Comparison of PWV and isoprostane content in patients. Consecutive 6 μm sections were stained with anti-CD3, D-11 ScFv, and Masson’s trichrome blue \((A)\). Images are ×20 magnification. Scale bars: 100 μm. Image J was used to quantify the area of D-11 staining for isoketal adducts and the area of blue in the Masson’s trichrome stains. Human T cells were quantified by counting positively stained cells per ×20 field \((B\ and\ C)\). Spearman’s correlations comparing PWV and 8-isoprostanes in normotensive and treated hypertensive humans \((E)\). M, media; A, adventitia.

(39), perhaps because ROS can have important signaling functions that modulate vascular tone, cell growth, and survival \((40–42)\) and are critical for innate immunity. We have previously shown that these higher concentrations of vitamin E are required to suppress plasma F2 isoprostanes, which form from the same precursors as isoketals \((43)\). It is therefore possible that agents such as 2-HOBA, which directly scavenge isoketals with a high rate constant and do not interfere with other ROS, will prove beneficial in treatment of disorders such as hypertension and aortic stiffening.

**Methods**

**Animals.** Male WT and \( \text{tg}^{\text{m/p22phox}} \) mice were studied at 3, 6, and 9 months of age. For measurement of blood pressure, 6 mice at each

to the staining of surface markers. The antibodies used were: AmCyan anti-CD45 (clone 2D1, BD Biosciences), PE anti-F4/80 (clone BM8, eBioscience), Pacific Blue anti-CD19 (clone 6D5, BioLegend), APC-Cy7 anti-CD3e (clone 145-2C11, BD Biosciences), APC anti-CD4 (clone GK1.5, eBioscience), and PE-Cy7 anti-CD8α (clone 53-6.7, BD Biosciences). Cells (1 × 10⁶) were incubated with 1.5 μl of each antibody in 100 μl of FACS buffer for 35 minutes. The cells were then washed twice with FACS buffer and immediately analyzed on a FACS-Canto flow cytometer with DIVA software (BD Biosciences). Dead cells were excluded from analysis using 7-AAD (catalog 559925, BD Biosciences). For each experiment, we performed flow minus one (FMO) controls for each fluorophore to establish gates. Data analysis was performed using FlowJo software (Tree Star Inc.).

Intracellular staining of splenocytes. Splenocytes (1 × 10⁶) were resuspended in RPMI medium supplemented with 5% FBS and stimulated with ionomycin and phorbol myristate acetate and brefeldin A at 37°C for 5 hours. Dead cells were excluded from analysis with a fixable Violet dead cell stain. The following surface antibodies were employed for staining T cells: BV510 anti-CD45 (clone 2D1, BD Biosciences), PerCP-Cy7 anti-CD3e (clone 145-2C11, BD Biosciences), APC-Cy7 anti-CD8α (clone 53-6.7, BD Biosciences), and APC-PerC-Cy7 anti-CD4 (clone GK1.5, BD Biosciences). Intracellular staining was then performed with the Cytofix/Cytoperm Plus fixation/permeabilization solution kit (BD Biosciences) using PE anti-IL-17A (clone eBio17B7, eBioscience), and FITC anti–IFN-γ antibodies (clone XMG1.2, eBioscience). In some experiments, macrophages, DCs, and monocytes were gated using APC anti-CD11b (clone M1/70, BD Biosciences), PE anti-MerTK (clone HMERS5DS, eBioscience), APC-Cy7 anti-CD11c (clone HL3, BD Biosciences), PerCP-Cy5.5 MHC-II/II-A b (clone M5/114.15.2, BD Biosciences), PE-Cy7 anti-CD64 (clone X54-5/71, BioLegend), AmCyan anti-F4/80 (clone BM8, BioLegend), and Alexa Fluor 700 anti-Ly-6C (clone AL-21, BD Biosciences) as previously described (25). A single chain antibody, D11 ScFv, was conjugated to Alexa Fluor 488 (catalog A10468, Invitrogen) for the detection of isoketals in these cells.

Measurement of isoketals. Isoketals in mouse aortas were also measured as the isoketal-lysyl-lactam adducts using MS analysis as previously described (18, 48). To detect DC isoketal addeducted peptides by dot blot analysis, DCs from the spleen of 9-month-old WT or tgsm/p22phox mice were sorted using a Miltenyi Biotec DC isolation kit to positively select IAb+/CD11b+/CD11c+ cells. The cells were placed in citrate-phosphate buffer at pH 3.3 containing a protease inhibitor cocktail and iodoacetamide (1:100) to elute MHC-bound peptides. The peptides were then passed through ultrafiltration devices (Amicon Ultra, Millipore) to isolate peptides <5,000 Da and to remove β2-microglobulin proteins. Dot blot analysis was carried out on the resulting flow-through to detect isoketal-addeducted peptides using D11 ScFv.

T cell proliferation assay. Aorta homogenates were obtained from WT mice, tgsm/p22phox mice, or tgsm/p22phox mice chronically treated with tempol or 2-HOBA. Protein concentrations were determined in these samples using Bradford assay. CD11c+ DCs were isolated from total splenocytes of WT mice using a magnetic cell sorter and a commercially available kit (Miltenyi Biotec). This is an acceptable method to isolate essentially all DCs from mouse splenocytes. One million DCs were exposed to 100 mg aortic protein for 2 hours in RPMI 1640 with 10% FBS, 5% penicillin/streptomycin/fungizone, and 5% sodium pyruvate. These DCs were washed twice before being cocultured for 7 days with pan T cells prelabeled with CFSE (catalog C34554, Invitrogen). T cells were obtained from 9-month-old WT mice or tgsm/p22phox mice that had either been untreated or chronically treated with tempol or 2-HOBA in the drinking water. Various combinations of aorta homogenate and T cells were employed as described in Figure 9, A and B. These cells were subjected to flow cytometry analysis, and cytokines in the culture medium were measured by luminex.

The Journal of Clinical Investigation

Figure 14. Proposed pathway. Chronic vascular oxidative stress leads to formation of immunogenic isoketal-protein adducts, which accumulate in DCs and promote T cell activation. Activated T cells accumulate in perivascular tissues and release cytokines that enhance collagen deposition and aortic stiffening. This enhances pulse wave velocity. Renal inflammation and fibrosis follows these events, leading to overt hypertension.

IHC of mouse tissues. Consecutive 6-micron sections were obtained from paraffin-embedded mouse thoracic aorta and kidney. These sections were stained with anti-CD3 (clone 145-2C11, BD Biosciences), D-11 ScFv, and Masson’s trichrome blue as previously described (18, 49). Image J was used to quantify the area of D-11 staining for isoketal adducts and the area of blue in the Masson’s trichrome stains per 20× field.

Human studies. PWV was measured using the SphygmoCor System (AtCor Medical). Venous blood samples were collected in tubes containing heparin. Plasma 8-isoprostane was detected by an enzyme immunoassay EIA kit (Cayman Chemical).

Human aortic tissue samples were obtained by one of the authors (J.A. Curci) during the course of open revascularization procedures for atherosclerotic occlusive disease of the aorta or at the time of renal transplantation at Washington University, St Louis, Missouri, USA. All specimens were full thickness infrarenal aortic tissue that was discarded at the time of the procedure by the clinical team and were anonymously transferred to the laboratory for study. Portions of these tissue samples were fixed in formalin, embedded in paraffin, and sliced into 6-micron sections. Consecutive sections were stained with anti-CD3 (clone HITT3a, BD Biosciences), D-11 ScFv, and Masson’s trichrome blue as previously described (18, 49). Human T cells were quantified by counting the number of positively stained cells per 20× field. Five representative fields were quantified for each sample.

Statistics. Data in the manuscript are represented as mean ± SEM. Comparisons of blood pressure over time and aortic mechanics were made using 1-way ANOVA for repeated measures, followed by a Bonfer-roni post hoc test when significance was indicated. To compare the effect of age on various mouse strains, 2-way ANOVA was employed. To compare the effects of antioxidant treatments and the effect of Rag-1 deficiency, 1-way ANOVA was performed. The values of cytokines were normalized with logarithmic transformation prior to 1-way ANOVA. Correlations between immune-staining parameters were made using Spearman’s correlation analysis. Multivariate regression was used for analysis of human data. P values are reported in the figures.

Study approval. All animal procedures were approved by Vanderbilt University’s Institutional Animal Care and Use Committee, and the mice were housed and cared for in accordance with the Guide for the Care and Use of Laboratory Animals, US Department of Health and Human Services. The institutional review boards of Washington University and the University of Campinas approved the respective human studies. Subjects enrolled at Campinas signed a written informed consent form before enrolling in the study.

Author contributions. JW, MAS, AK, HAI, KRCM, LX, WC, SSD, and NRB performed experiments, analyzed data, and participated in manuscript preparation. SSD and LJR performed MS. JG, CMW, KEB, LJR, HM, HC, MSM, and DGH participated in study design and manuscript preparation and obtained funding for the study. JAC provided human samples and assisted in manuscript preparation. HM supervised and obtained funding for human studies of PWV. RLM produced and provided the D11 antibody and assisted in experimental design.

Acknowledgments. We are grateful to the Transitional Pathology Shared Resource (TPSR) core and the Epithelial Biology Center at Vanderbilt University for assistance with imaging and quantification of immunohistochemical staining. We also thank the Vanderbilt University Medical Center Hormone Assay and Analytical Services Core (supported by NIH grants DK059637 and DK020593), who performed the cytokine measurements. We thank William Zackert for performing the MS and IHC for isoketal in the aorta samples. We also thank Zhihong Wang in the Division of Cardiovascular Medicine at Vanderbilt University for his assistance in conducting in vivo measurement of PWV. This work was supported by NIH R01 grants HL105294, HL039006, and HL108701; VITA contract HHSN268201400010C; Program Project grants P01 HL58000 and GM015431; an American Heart Association predoctoral fellowship to J. Wu (13PRE14480008); and postdoctoral fellowship awards to A. Kirabo and M.A. Saleh. M.S. Madhur is the recipient of NIH K08 award (1K08HL121671) and a Vanderbilt Physician Scientist Development Award. H.A. Itani is supported by NIH F32 training grant (1F32HL124972-01).
