**Aging**

Hutchinson-Gilford progeria syndrome (HGPS) is a rare autosomal dominant genetic disease that is caused by a silent mutation of the *LMNA* gene encoding lamins A and C (lamin A/C). The G608G mutation generates a more accessible splicing donor site than does WT and produces an alternatively spliced product of LMNA called progerin, which is also expressed in normal aged cells. In this study, we determined that progerin binds directly to lamin A/C and induces profound nuclear aberrations. Given this observation, we performed a random screening of a chemical library and identified 3 compounds (JH1, JH4, and JH13) that efficiently block progerin–lamin A/C binding. These 3 chemicals, particularly JH4, alleviated nuclear deformation and reversed senescence markers characteristic of HGPS cells, including growth arrest and senescence-associated β-gal (SA–β-gal) activity. We then used microarray-based analysis to demonstrate that JH4 is able to rescue defects of cell-cycle progression in both HGPS and aged cells. Furthermore, administration of JH4 to *Lmna*G609G/G609G-mutant mice, which phenocopy human HGPS, resulted in a marked improvement of several progeria phenotypes and an extended lifespan. Together, these findings indicate that specific inhibitors with the ability to block pathological progerin–lamin A/C binding may represent a promising strategy for improving lifespan and health in both HGPS and normal aging.

Hutchinson-Gilford progeria syndrome (HGPS) is a rare autosomal dominant genetic disease that is caused by a silent mutation of the LMNA gene encoding lamin A and C (lamin A/C). The G608G mutation generates a more accessible splicing donor site than does WT and produces an alternatively spliced product of LMNA called progerin, which is also expressed in normal aged cells. In this study, we determined that progerin binds directly to lamin A/C and induces profound nuclear aberrations. Given this observation, we performed a random screening of a chemical library and identified 3 compounds (JH1, JH4, and JH13) that efficiently block progerin–lamin A/C binding. These 3 chemicals, particularly JH4, alleviated nuclear deformation and reversed senescence markers characteristic of HGPS cells, including growth arrest and senescence-associated β-gal (SA−β-gal) activity. We then used microarray-based analysis to demonstrate that JH4 is able to rescue defects of cell-cycle progression in both HGPS and aged cells. Furthermore, administration of JH4 to Lmna<sup>−/−</sup>/C<sup>−/−</sup>-mutant mice, which phenocopy human HGPS, resulted in a marked improvement of several progeria phenotypes and an extended lifespan. Together, these findings indicate that specific inhibitors with the ability to block pathological progerin–lamin A/C binding may represent a promising strategy for improving lifespan and health in both HGPS and normal aging.

Introduction

Hutchinson-Gilford progeria syndrome (HGPS) is an extremely rare disease that recapitulates some aspects of physiological aging (1–5). Accordingly, a detailed understanding of the molecular mechanisms underlying HGPS may be useful for the prevention of aging or aging-related diseases. In fact, it has been shown that progerin, a gene product of HGPS cells derived from an aberrant splicing process (6, 7), is also detected in non-HGPS aged cells (8, 9). Progerin expression induces several changes in cellular morphology, such as nuclear membrane blebs and a reduction of nucleoplasmic lamin A (10, 11), whereas progerin downregulation rescues nuclear deformation (10, 12), indicating that progerin gain of function is a causal factor for HGPS. It has also been reported that progerin accumulates in several human cancer cells (13, 14) and induces nuclear deformation (9–11). Notably, expression levels of progerin and lamin A and C (lamin A/C) are significantly reduced in induced pluripotent stem cells (iPSCs) derived from patients with HGPS (15, 16). Likewise, cellular senescence markers, including nuclear deformation, histone e H3 trimethyl Lys9 (H3K9Me3) and senescence-associated β-gal (SA−β-gal), are also decreased in these cells. By contrast, differentiated HGPS cells re-express senescence markers following progerin expression (15).

Despite several reports dealing with the role of this protein in cell-cycle regulation (11, 17, 18) and senescence (12, 19), how progerin induces various cellular defects and premature aging remains to be revealed. Remarkably, proteomic studies and 2-hybrid approaches have identified lamin A/C as a progerin-binding protein (20, 21). On this basis, we hypothesized that the interaction of progerin with lamin A/C contributes to the development of the senescence phenotype of HGPS and aged cells.

Results

Direct interaction between progerin and lamin A/C but not lamin B. To investigate our hypothesis, we performed a binding assay and found that C-terminal progerin and lamin A associated with lamin A and C but not with lamin B1 (Figure 1A and Supplemental Figure 1A; supplemental material available online with this article; doi:10.1172/JCI84164DS1). In addition, the binding affinity between progerin and lamin A/C was stronger than that between lamin A/C and lamin A/C (Figure 1B and Supplemental Figure 1B). To dissect the progerin domain involved in lamin A/C binding, we performed a glutathione-S-transferase pull-down (GST pull-down) assay using a His-tagged lamin A N-terminal region (LMNA-N; aa residues 1-300) and a lamin A middle region (LMNA-M; aa residues 301-564) with bead-coupled GST-C-terminal fragments of lamin A (GST-LMNA) or progerin (GST-progerin). We found that the middle region of lamin A was responsible for progerin binding (Figure 1, C and D). We could confirm the direct interaction of both proteins through Far Western blot
lamins A and C formed an irregular fiber arrangement (Supplemental hypothesis was consistent with the HGPS cell phenotype, in which but irregular bundle formation than does lamin A or C alone. This amendments by head-to-tail binding and bundle through the C-terminal region of LMNA is a target of progerin. By ELISAs with an immobi-

ied proteins were analyzed by Western blotting. N, LMNA-N; M, LMNA-M. (D) Scheme of the interaction between lamin A and progerin. (E) ELISA results. His-tagged LMNA-M was fixed in a 96-well plate and incub-

ated with GST-LMNA or GST-progerin. Photograph of the 96-well plate (inset) and ELISA value. (F and G) Progerin did not induce nuclear deforma-
in neutrons or embryonic neuron cells. Transfection of GFP-progerin or lamin A alone into the neuroblastoma cell line SH-SY-5Y (M) could block 50% of 

of lamin A self-association (Supplemental Figure 2E).

The effect of progerin–lamin A binding inhibitors in HGPS model cells. To confirm the inhibitory effect of JH chemicals on binding between progerin and lamin A, we performed the GST pull-down assay and observed that JH4 blocked the interaction of GST–lamin A with GFP-progerin, but not with GFP–lamin A, in a GST pull-down assay using cell lysates (Figure 2A and Supplemental Figure 3A). However, the farnesyltransferase inhibitor FTI-277, known to ameliorate nuclear deformation (23, 24), did not show an obvious effect on progerin–lamin A binding (Figure 2A and Supplemental Figure 3B). Next, we checked their in vivo effect in progerin and GFP–lamin A–transfected HEK293 cells through IP assays with an anti-GFP Ab. The binding between progerin and lamin A was markedly reduced by the JH chemicals, while the binding between lamin A and lamin B was not affected by these compounds (Figure 2B). Additionally, a reduction of p16ink4a expression was detected in response to treatment with the JH chemicals (Figure 2B). We also observed the different localization of progerin from that of lamin A upon JH4 treatment (Figure 2C and Supplemental Figure 3C). Moreover, all these JH compounds, and in particular JH4, blocked nuclear deformation (Supplemental Figure 4, A and B). These results indicate that JH4 (and JH13 to some extent) blocked the interaction between progerin and lamin A and alleviated progerin-induced nuclear deformation. However, JH4 did not show any significant effect on the localization pattern of other lami-
nopathy-related lamin A mutants (2) such as nuclear speckles of D192G (Supplemental Figure 4C). This result also supports the idea that JH4 possesses selective activity on progerin. Next, we examined the effect of JH chemicals on HGPS cells. Consistent with the above results, JH chemicals, in particular JH4, blocked the interaction between progerin and lamin A in these progeroid cells (Figure 2D and Supplemental Figure 4D), without alteration of progerin mRNA expression (Supplemental Figure 4E). In addition, JH chemicals, and especially JH4, ameliorated the frequency of nuclear deformation of HGPS cells (Figure 2, E and F, and Supplemental Figure 4, F and G).

Specific interaction of JH4 and progerin. To determine the direct target of JH chemicals, we monitored their effect on the previously observed progerin-p14arbif binding (14). In this assay, we found that JH chemicals blocked the interaction between progerin and p14arbif (Supplemental Figure 5A), but not between p53 and p14arbif (ref. 25 and Supplemental Figure 5B). In addition, JH4 did not block the interaction between progerin and MEL18/BMI1 that is achieved by the middle region of lamin A (ref. 26 and Supplemental Figure 5, C-E). Considering these facts, the C-terminal region of progerin may be the direct target of JH4 (Supplemental Figure 5F). To verify this hypothesis, we generated biotinylated JH4 (Supplemental Figure 5G; B33: precursor for biotinylation; 07: biotinylated JH4; 08: biotin plus linker). Modified chemicals showed inhibitory activity similar to that of JH4 on binding between lamin A and progerin (Supplemental Figure 5H) as well as on nuclear deformation (Fig-

analysis (Supplemental Figure 1C). Considering that progerin can strongly interact with LMNC (which corresponds to aa 1-572 of LMNA), we excluded the possibility that the C-terminal extension region of LMNA is a target of progerin. By ELISAs with an immobilized LMNA-M domain and the GST-fused recombinant lamin A or progerin, we could estimate that progerin–lamin A binding affinity is more than 2-fold stronger than that of lamin A–lamin A binding (Figure 1E). Considering that lamin A and C form intermediate fil-

aments by head-to-tail binding and bundle through the C-terminal and middle regions (22), progerin may induce a stronger or tighter but irregular bundle formation than does lamin A or C alone. This hypothesis was consistent with the HGPS cell phenotype, in which lamins A and C formed an irregular fiber arrangement (Supplemental Figure 1, D and E). Indeed, progerin alone did not induce nuclear deformation in lamin A/C-deficient neuron or embryonic neuron cells, whereas cotransfection with lamin A could induce it (Figure 1, F and G, and Supplemental Figure 1, F and G), despite low expression of progerin in N2A cells (Supplemental Figure 1G). These results indicated that nuclear lamina alteration can derive from the strong binding of progerin to lamins A and C.

Screening of specific binding inhibitor of progerin–lamin A binding. The above findings prompted us to search for putative progerin/lamin A-binding inhibitors by using an ELISA-based screening system. In brief, progerin, immobilized in 96-well plates, was incubated sequentially with a chemical library and His–lamin A (Supplemental Figure 2, A and B). This screening identified 5 chemicals that blocked this interaction (JH1, JH4, JH13, LG-02, and KEK-2-24, Supplemental Figure 2C). Because KEK-2-24 is a mixture of compounds from Panax ginseng and LG-02 requires complicated synthetic steps, we excluded them from further study. A detailed synthetic pathway for the selected chemicals is described in the Chemical Synthesis section of the Supplemental Methods. Interestingly, in spite of the blind screening, the selected chemicals were structurally similar (Supplemental Figure 2C) and showed very low cytotoxicity (Supplemental Figure 2D). Therefore, we decided to further investigate the activity of JH chemi-
cals, particularly JH4, because JH1 and JH13, despite their similar effects, show very low solubility. We first confirmed their inhibitory effect of the JH chemicals on the binding between progerin and lamin A through in vitro binding assays (Supplemental Figure 2E). Indeed, less than 1 μM of JH4 (IC 50 = 0.65 μM) could block 50% of the interaction between progerin and lamin A without disruption of lamin A self-association (Supplemental Figure 2E).
Figure 2. Ameliorating effect of JH chemicals on nuclear deformation. (A) Specific effect of JH chemicals on the binding of lamin A–progerin but not on that of lamin A–lamin A. GST pull-down assay using lysates from HEK293 cells transfected with GFP-LMNA after incubation with GST-LMNA or GST-progerin under treatment with the indicated chemicals. (B) Dissociation of lamin A and progerin by JH4 in human cells. Dissociation of progerin from lamin A/C was confirmed by IP in HEK293 cells. For this, GFP-progerin–transfected HEK293 cells were incubated with the indicated chemicals (5 μM) for 24 hours. A reduction of p16INK4A was also detected in whole-cell lysate. Actin was used as a loading control. SUP, supernatant. (C) JH4 blocked the colocalization of lamin A and progerin. For this, HEK293 cells were cotransfected with GFP-LMNA and nontagged progerin (NT progerin) for 24 hours and incubated with JH4 for an additional 24 hours. JH4 could abolish the colocalization of lamin A and progerin (red) in the nuclear membrane or in nuclear speckles. DAPI was used for DNA staining. Scale bar: 10 μm. (D) JH4 blocks the interaction of lamin A and progerin in HGPS cells. Treatment with 5 μM JH4, but not FTI-277, for 24 hours blocked the interaction of lamin A and progerin in HGPS cells. Cell lysates were immunoprecipitated with a lamin A–specific Ab (H-102, sc-20680) and immunoblotted with a progerin-specific Ab. Normal cells (9 yr; N9) were used as a negative control for progerin. (E) Effect of JH chemicals on nuclear deformation of HGPS cells. Three kinds of HGPS cells were incubated with the indicated chemicals for 24 hours and fixed for lamin A/C immunofluorescence analysis (green). The same effect was observed in other HGPS cells (Supplemental Figure 4F). Scale bars: 10 μm. (F) Quantification of nuclear abnormalities in HGPS cells. JH chemicals, in particular JH4, ameliorated nuclear deformation of HGPS cells. P values were determined by Student’s t test. PPT, protein pellet.

Figure 3. Antisenescence effect of JH chemicals on normal aged human fibroblasts. Since progerin-induced nuclear deformation is also observed in aged cells, we hypothesized that the JH chemicals may also decelerate the normal aging process. To address this, we checked the expression of progerin in normal fibroblasts obtained from an 81-year-old donor (N81). These cells expressed progerin at the transcriptional level (Supplemental Figure 7A) and showed abnormal nuclear morphology, similar to what was observed in HGPS cells (Supplemental Figure 7B; arrowheads). These results, together with previous reports showing that progerin accumulates in aged cells and causes nuclear deformation (8, 9), prompted us to hypothesize that the JH chemicals could prevent senescence of aged cells. Indeed, the nuclear morphology of the 81-year-old cells was clearly improved by JH chemicals and FTI-277 (Figure 5A and Supplemental Figure 7C). Moreover, the slow proliferation of normal 81-year-old fibroblasts was completely rescued by JH4 (Figure 5B). To check the possible long-term toxicity of this treatment, we incubated fibroblasts from young, old, and HGPS human tissues with JH4 for 10 days and found that this compound could promote cell growth and colony formation without obvious toxicity (Supplemental Figure 7 D and E). In SA–β–gal assays, we also observed that JH4 could block cellular senescence (Figure 5C). Consistently, expression of Ki-67 (30), a cell proliferation marker, was increased after JH4 treatment (Supplemental Figure 7F). Additionally, increased H3K9Me3 (Figure 5D) and reduced DcR2 and p16INK4A levels were detected by JH4 treatment in normal aged fibroblasts (Figure 5E). Thus, we next checked the effect of JH4 on oncogene-induced or growth factor–induced senescence (31, 32). Senescence induced by IGF-1 treatment or transfection of oncogenic Ras into WI-38 (normal foreskin fibroblast) was not blocked by JH4 (Supplemental Figure 7, G and H), because oncogene-induced senescence did not induce progerin (Supplemental Figure 7I), nor was induction of p16 blocked by JH4 treatment (Supplemental Figure 7I). In addition, JH4 did not promote cell viability in human cancer cell lines, despite a 72-hour treatment (Supplemental Figure 8A), suggesting that the antisenescence effects of JH4 do not result in the promotion of cancer progression. Instead, JH4 could ameliorate the nuclear deformation in renal cell carcinoma induced by progerin expression (Supplemental Figure 8B), with slight growth suppression at a high concentration (Supplemental Figure 8C). These results suggest that JH chemicals, in particular JH4, selectively block progerin-mediated senescence, without growth promotion of progerin-negative cells.

Figure 4. Restoration of aging-related gene expression profile by JH4 treatment. To gain further insight into the biological effects of JH4, we investigated its impact on gene expression profiles. For this purpose, we hybridized oligonucleotide microarrays with RNA samples from HGPS-1, JH4-treated HGPS, young (9-year-old; N9), and old (81-year-old; N81) fibroblasts. Among 14,400 genes

Figure 5. JH chemicals ameliorate nuclear abnormalities in HGPS cells. JH chemicals, in particular JH4, ameliorated nuclear deformation of HGPS cells. P values were determined by Student’s t test. PPT, protein pellet.
present in the array, 1,921 showed differential expression (cutoff of 2-fold; Figure 5A and Supplemental Figure 9A). After elimination of nonsignificant changes resulting from the comparison between HGPS and young cells (Supplemental Figure 9A and Supplemental Table 1), we classified differential genes in an HGPS unique gene set (HUG), an aging unique gene set (AUG), and an HGPS/aging-related gene set (HARG) (Figure 6A, Supplemental Figure 9B, and Supplemental Tables 2 and 3). Next, we defined a set of genes whose expression is restored by JH4 treatment (HARG/JR) (298 genes; Supplemental Figure 9B and Supplemental Table 3).
4). To verify these transcriptomic results, we confirmed that the expression of several genes such as \textit{IL33}, \textit{BRCA1}, \textit{BLM}, \textit{RAD51}, \textit{IL6}, \textit{IL8}, and tumor necrosis factor superfamily member 18 (\textit{TNFSF18}) was altered at both the protein and mRNA levels after JH4 treatment (Figure 6, B and C). By contrast, farnesyltransferase inhibitor (FTI) treatment did not revert the expression changes of the HARG/JR genes (Supplemental Figure 9C), indicating that the

**Figure 4. Antisenescence effect of the JH chemicals on HGPS cells.** (A) JH chemical overcame the growth suppression of HGPS cells. After seeding at $1 \times 10^4$ cells per well, cell proliferation was determined by cell counting every 48 hours for 6 days. The experiment was performed in triplicate. $^*P = 0.01$, $^{**}P = 0.016$. $P$ values were determined by Student’s t test. (B) Cell proliferation assay of normal cells obtained from a 9-year-old person (N9) under the same condition as above. JH4 could induce proliferation of normal cells, particularly at late time points (between 4 and 6 days). (C) Induction of Ki-67 by JH4 in HGPS cells. Three types of HGPS cells were incubated with JH4 for 48 hours and stained with Ki-67 Ab (red). Scale bars: 10 \textmu m. (D) JH chemicals suppressed SA-\beta-gal expression in HGPS cells. SA-\beta-gal assay of HGPS cells incubated with JH chemicals (5 \mu M, for 48 hours). The same result was obtained for other HGPS cells (Supplemental Figure 7A). Original magnification, x40. (E) JH4 suppressed the half-life of progerin. Pulse-chase analysis using the de novo synthesis inhibitor cycloheximide (CHX) showed a rapid reduction of progerin by treatment with JH4. Cells, transfected with GFP-LMNA or GFP-progerin vectors, were incubated with 10 \mu M CHX for the indicated durations, with or without 5 \mu M JH4. (F) The proteasome inhibitor ALLN blocked progerin downregulation by JH4. (G) JH chemicals induced H3K9Me3 in HGPS cells. Cells, incubated with the indicated chemicals (5 \mu M) for 48 hours, were fixed with 100% Me-OH and stained with anti-H3K9Me9 Ab (green). DAPI was used for DNA staining (blue). Scale bars: 10 \textmu m. Con, control.
effects of JH4 and FTI are markedly different. Since the alternation of gene expression is due to a different genetic background but not to aging, we examined the expression of several genes induced or suppressed in aged fibroblasts and HGPS cells in other kinds of human aged fibroblasts and different HGPS cells. Expression levels of IL33, RAD51, and BRCA1 were reduced in 3 kinds of aged fibroblasts (N81; N72, 72-year-old; and N94, 94-year-old) and HGPS-2 cells compared with the levels detected in fibroblasts from N9 (Supplemental Figure 9D). In contrast, IL6 and IL8 were overexpressed in these cells (Supplemental Figure 9D). This result suggested that alternation of these expression levels would result from aging. To investigate the biological significance of these transcriptional alter

---

**Figure 5. Antisenescence effect of JH chemicals on normal aged cells.** (A) Nuclear deformation of aged fibroblasts was ameliorated by JH4. Normal cells obtained from 9-year-old (N9) and 81-year-old (N81) subjects were incubated with JH4 (5 μM) for 48 hours and stained with anti-lamin A/C Ab (green). DAPI was used for DNA staining. Scale bars: 10 μm. (B) JH4 could induce cell proliferation in aged fibroblasts. After seeding 7.5 × 10^4 cells per well, cells were maintained for a maximum of 6 days with the indicated JH chemicals (5 μM). Cell numbers were calculated every 48 hours. The slow proliferation of cells from N81 compared with that of cells from N9 (Figure 4B) was completely rescued by JH4 treatment. *P = 0.013. The P value was determined by Student’s t test for analysis of statistical significance between 2 groups. (C) JH4 suppressed senescence of N81 fibroblasts. An SA-β-gal assay was performed on cells from N81 after treatment with the indicated chemicals (5 μM) for 48 hours. Original magnification, ×40. (D) JH4 induced H3K9Me3 expression in normal aged cells. Immunofluorescence for H3K9Me3 (green) was performed in N9 and N81 cells under treatment with the indicated chemicals (5 μM) for 48 hours. Scale bars: 10 μm. (E) JH4 suppressed DCR2 and p16^INK4A in normal human cells. Reverse transcriptase-PCR (RT-PCR) analysis of the indicated genes was performed in normal cell lines (N9, N29, and N81) after treatment with JH4 for 48 hours.
Figure 6. Aging-related gene expression is recovered by JH4 treatment. (A) Heatmap of gene expression profiles showing a difference of at least 2-fold in both cell lines. Colors represent values normalized to the range of intensity for each gene in all conditions. (B) Reduced expression of IL33, BRCA1, BLM, and RAD51 in HGPS cells was reverted by JH4. Conversely, IL6, IL8, and TNFSF18 overexpression was suppressed by JH4 treatment. (C) JH4 could alter HGPS-specific gene expression. RAD51, BRCA1, cyclin B1, and CDC25C protein expression levels were increased by treatment with JH4. (D) Network analysis using cBioportal. Genes in the HARG/JH group were clustered into chromosome separation, DNA replication, DNA repair, and cell-cycle groups. (E) JH4 overcame progerin-induced cell-cycle arrest. Cell-cycle arrest at the G2/M phase by progerin transfection was released by JH4 treatment (5 μM, for 24 hours).
Figure 7. JH4 prevents progeroid phenotypes in LmnaG609G/G609G mice. (A) Representative photographs of 8-week-old LmnaG609G/G609G mice (female, left; male, right) treated with JH4 (10 mg/kg twice per week). Mice were injected 8 times (from 4 weeks of age). (B) Increase in BW of LmnaG609G/G609G mice following JH4 injection. P values were determined by Student’s t test. (C) Increase in muscle strength following JH4 injection. Grip strength was measured for LmnaG609G/G609G, Lmna+/G609G, and Lmna+/+ male mice by pulling the spring balance after treatment with JH4 or vehicle alone. P value was determined by Student’s t test. (D) Growth morphology of thymus and spleen from 9-week-old LmnaG609G/G609G mice treated with vehicle or JH4. An obvious enlargement of both organs after JH4 treatment was observed. (E) JH4 injection time–dependent organ size increase. Compared with vehicle-injected mice, the size of several organs was gradually increased by treatment time. Numbers above each bar indicate the fold increase at each time point (see also Supplemental Figure 14). (F) JH4 injection promoted the cell cycle of splenocytes obtained from 7-week-old mice (injected 6 times). Cell-cycle promotion was observed in JH4-treated cells. (G) Rescue of cell and tissue defects. Foot pad skin was thickened and dermal connective tissue was enriched in JH4-treated animals (upper panels). Kidney tissue was well organized after JH4 treatment. Tissues were obtained from 18-week-old (vehicle) and 22-week-old (JH4) mice. Scale bar: 80 μm. (H) Increase in cell density and reduction of deformed cell nuclei in JH4-treated heart tissue obtained from the same mice above. On the basis of the histology, nuclear morphology (right) and cell density (left) were counted for 3 different mice and 5 different regions per mouse by 3 researchers. P values were determined by Student’s t test. (I) Representative images of heart muscle. Arrows indicate deformed nuclei. Scale bar: 10 μm. (J) JH4 suppressed progerin and induced RAD51 and phosphorylated CDK2 (p-CDK2). Western blot analysis was performed using extracts from liver and kidney tissue obtained from 18-week-old sibling mice.

In order to analyze the altered gene networks using cBioPortal (33, 34) and found that many genes in the HARG/JR group were clustered in 4 functional categories: chromosome segregation, cell cycle, DNA repair, and DNA replication (Figure 6D). For example, genes encoding BUB1 (budding uninhibited by benzimidazoles 1), shugoshin-like 1 (SGOL1), centromere protein (CENP) family proteins (chromosome segregation), cyclin B2, cyclin-dependent kinase 1 (CDK1) (cell cycle), BRCA1, BRCA2, RAD51 (DNA repair), and minichromosome maintenance protein complex (MCM) family proteins were listed in this group (Supplemental Figure 9, E and F). On the basis of gene function, we grouped all JH4-responding genes into 18 categories (Supplemental Figure 9G). Consistent with what we observed with the protein network, the majority of HARG/JR was clustered in the cell cycle, DNA replication, chromosome regulation, and DNA repair. In agreement with these findings, JH4 could overcome the progerin-induced cell-cycle arrest, in particular at the G2/M phase (Figure 6E).

JH4 blocks progerin-induced lamin A aggregation in ER during the G2/M phase. Because many of the JH4-responsive genes shown in Supplemental Table 4 and Figure 4B are involved in cell-cycle and chromosome regulation and progerin induces cell-cycle arrest at the G2/M checkpoint (Figure 6E), we examined the effect of JH4 on the behavior of lamin A at the G2/M phase. Dispersal of lamin A upon treatment with Taxol (paclitaxel) was observed in young, but not aged, cells. Rather, lamin A surrounded chromosomal or nuclear DNA (Supplemental Figure 10A, white arrows). However, treatment with JH4 could promote lamin A elimination in aged cells (Supplemental Figure 10A, yellow arrows). We also observed that progerin-induced lamin A aggregation in nocodazol- or Taxol-treated cells was abolished by JH4, but not by FTI-277 (Supplemental Figure 10, B and C). To gain further insight into this observation, we analyzed the localization of progerin in nocodazol- or Taxol-treated cells. Cytoplasmic aggregates in nocodazol- or Taxol-treated cells were undetectable upon JH4 treatment, but not after incubation with FTI-277 (Supplemental Figure 11A). Given the role of the ER in nuclear lamina remodeling during the G2/M phase (23), we investigated the subcellular localization of lamin A and an ER-specific marker (35) in JH4-treated cells and found that aggregates of lamin A in the ER disappeared after JH4 treatment (Supplemental Figure 11B). Next, we checked the location of progerin after arrest at the M phase by Taxol treatment and found that JH4 also blocked ER-associated progerin during the M phase (Supplemental Figure 11C). To confirm whether M-phase aggregates contain lamin A–progerin complexes, we costained lamin A–GFP and progerin in Taxol-treated cells. Colocalized lamin A and progerin in the non-nuclear region was abrogated by JH4 (Supplemental Figure 11D). This result indicates that progerin disrupts lamin A dissemination and reduction during the G2/M phase by direct binding to this nuclear envelope protein. Indeed, it has been recently reported that HGPS cells show downregulated and defective poly(ADP-ribose) polymerase 1 (PARP1) in G2/M-phase progression (36).

Therapeutic effect of JH4 on the HGPS mouse model. To evaluate the therapeutic potential of JH4 in vivo, we injected i.p. 10 mg/kg of this compound twice per week into 4-week-old LmnaG609G/G609G HGPS mice, a suitable murine model of human HGPS (37). After 4 weeks of treatment, we observed a significant increase in BW (Figure 7, A and B), which continuously increased out to 12 weeks (Supplemental Figure 12A). By contrast, vehicle-treated mice showed a significant decrease in BW after the eighth week (Figure 7B and Supplemental Figure 12A). At 11 to 12 weeks, the difference in BW between vehicle- and JH4-treated mice reached 4 g (about 25%; Supplemental Figure 12A). In addition, injection of JH4 increased grab strength (Figure 7C) and suppressed hair loss at week 15 (Supplemental Figure 12B). Consistently with the increase in BW, the size of different organs was increased by JH4 administration (Figure 7D). Moreover, organ size recovery was fully dependent on the number of injections given (Figure 7E and Supplemental Figure 13), such that 5 weeks after the start of treatment (10 injections), thymus and spleen volumes were enlarged by approximately 2-fold when compared with tissues from vehicle-treated mice (Figure 7E). Since progerin induces a cell-cycle arrest that seems to be critical for growth retardation (17, 18, 37), we also analyzed cell-cycle dynamics and found that it was also promoted by JH4 (Figure 7F and Supplemental Figure 12C) in a number of injection-dependent ways (Supplemental Figure 13, A7 and B7). Histological analysis revealed that JH4 increased skin thickness, reduced kidney destruction, and alleviated nuclear deformation (Figure 7G and Supplemental Figure 12D). To obtain more detailed evidence, we measured the cell density and frequency of deformed nuclei in heart (Figure 7, H and I), liver (Supplemental Figure 12E), lung (Supplemental Figure 12F), and kidney (Supplemental Figure 12G). In all examined tissues, JH4 treatment increased cell density and reduced the number of deformed nuclei. For example, the reduction in cell numbers in the same region or in tubes and...
Figure 8. Lifespan extension in progerin-expressed mice. (A) Representative photograph of 40-week-old Lmna+/G609G control or JH4-treated mice. (B) BW of 40-week-old Lmna+/G609G control and JH4-treated mice. (C) In vivo effect of JH4 on binding between progerin and lamin A/C. Lmna+/G609G mice that received a single injection of JH4 (10 mg/kg) were sacrificed for IP analysis of liver and kidney. After 6 hours, JH4 could disrupt the interaction of progerin and lamin A. After 24 hours, dissociation of progerin and lamin A was detected in kidney. Extracted proteins were immunoprecipitated with progerin Ab, and the precipitated proteins were subjected to Western blotting with anti–lamin A/C or anti-progerin Ab. (D) Detection of JH4 in liver. Biotin-JH4 was injected into Lmna+/G609G mice, and liver lysates were reacted with streptavidin beads. Precipitated proteins were analyzed by Western blotting. (E) Kaplan-Meier survival plots for Lmna+/G609G mice treated with JH4 (n = 13) or with vehicle alone (n = 11). (F) Kaplan-Meier survival plots for Lmna+/G609G mice treated with vehicle (n = 6) or JH4 (n = 10). (G) Extension of lifespan by high-dose injection of JH4. A dose of 20 mg/kg JH4 could extend lifespan by as much as 26 weeks. (B and E-G) P values were determined by Student’s t test.

In summary, in this study, we have identified 3 compounds, JH1, JH4, and JH13, that efficiently block progerin–lamin A/C binding by JH4 in liver at 6 hours was observed after 24 hours in kidney. We were able to recover the progerin-binding biotin-JH4 (labeled “07” in Figure 8D) in liver 6 hours after injection, indicating, as we expected, that JH4 could work in an in vivo system.

JH4 extends lifespan in the progerin mouse model. Next, we assessed the lifespan of Lmna+/G609G progeroid mice after JH4 injection. As shown in Figure 8E, the lifespan of JH4-treated progeroid mice was extended by more than 4 weeks compared with that of vehicle-treated mice. Although JH4 treatment did not fully overcome the short lifespan of these animals, considering the low concentration (10 mg/kg) and frequency (2 times/week) of administration, it appears to have a promising effect. In fact, JH4 also significantly extended the lifespan of Lmna+/G609G heterozygous mice (Figure 8F). Since biological effect of JH4 was dose-dependent, we injected 20 mg/kg JH4 into Lmna+/G609G progeroid mice. From this experiment, we found that 20 mg/kg JH4 could extend lifespan by as much as 26 weeks (Figure 8G). These results suggest that if JH4 can be retained at a higher concentration, lifespan could be more dramatically extended and that JH4 would be a strong therapeutic drug candidate for the treatment of HGPS.

Discussion

The aging process is complicated, and a full understanding of the molecular mechanisms controlling it is not likely to be realized in the near future. However, some basic clues are known from studying human progeria syndromes such as HGPS (39–41). Although HGPS is caused by progerin, a product of a point mutation in the LMNA gene, progerin is also expressed in normal aged cells as well as in cancers (14). Thus, understanding the pathological function of progerin is useful for the development of a therapeutic strategy to treat HGPS as well as for the prevention of aging.

In fact, over the past decade, the farnesylation of progerin has been targeted for drug development to treat HGPS. (24, 42). Because the farnesylated domain of progerin rigidly anchors it to the nuclear membrane, it may induce nuclear deformation. Blocking farnesylation by FTIs in HGPS cells restores nuclear morphology, cell proliferation, and heterochromatin organization. Moreover, treatment with FTIs in HGPS-like mouse models improves lifespan, growth, and BW and relieves premature aging symptoms such as bone defects (23). In particular, FTIs can extend the lifespan of Zmpste24–/− mice (24). However, a clinical trial of FTI did not produce promising results (43), indicating that other targets should be explored.

In this study, we found that the most important target of progerin is lamin A/C. Indeed, progerin shows strong binding affinity for lamin A/C but not lamin B (Figure 1E). On this basis, we found new chemicals that can block the interaction between progerin and lamin A/C through direct interaction with progerin (Figure 2B and Figure 3E). Since the chemical JH4 can bind selectively to progerin, there would be very minimal, nonspecific side effects. In our study, JH4 did not show an effect on the progerin-independent progeria model (Zmpste24–/− mice; Supplemental Figure 14C) or on mouse and monkey cell lines (data not shown). These results indicate that JH4 has potential use as a progerin-inhibitory drug.

Although JH4 did not fully overcome the short lifespan of the Lmna+/G609G mouse model, given the low dose and frequent injections of the compound, an optimized treatment strategy using JH4 could offer an effective therapy. Indeed, the same scheduled injection produced more obvious effects in Lmna+/G609G mice (Figure 8), and JH4 appeared to be excreted within 24 hours.

In summary, in this study, we have identified 3 compounds, JH1, JH4, and JH13, that efficiently block progerin–lamin A/C interaction time–dependent manner (Figure 7J, Supplemental Figure 13, C). Consistent with our microarray data described above, the expression level of these genes was restored by JH4 treatment in an injection time–dependent manner (Figure 7), Supplemental Figure 13, A8 and B8). Moreover, progerin expression was reduced to undetectable levels (Figure 7J).

Specific effect of JH4 on progerin-expressing mice. Because Lmna+/G609G progerin heterozygous mice also exhibit progeroid features, we checked the effect of JH4 on these animals and found that injection of JH4 (twice/week) over a 20-week period also ameliorated a number of aging phenotypes present in these mice, such as loss of BW (Figure 8, A and B, and Supplemental Figure 14A) and dermal and heart muscle alterations (Supplemental Figure 14B). Moreover, treatment of Lmna+/G609G mice with JH4 could result in recovery of their BW to that of normal mice (Figure 8B).

To investigate whether the in vivo antiprgerin effects of JH4 are due to the inhibition of progerin–lamin A binding or to an unknown side effect of this compound, we decided to test JH4 in a progerin-independent progeria model, namely the zinc metallopeptidase STE24-deficient mouse (Zmpste24−/−) (38), in which the progeroid phenotype is caused by prelamin A rather than by progerin accumulation. Despite the nearly identical progeroid phenotype of Zmpste24−/− and Lmna+/G609G mice, JH4 did not produce any noticeable change of growth in Zmpste24−/− mice (Supplemental Figure 14C), demonstrating that the antiacelerated aging activity of JH4 is directly related to its inhibition of progerin’s deleterious effects. Indeed, the interaction between progerin and lamin A/C in tissues was disrupted by a single JH4 injection (Figure 8C), following its metabolic tract. Disruption of progerin–lamin A/C binding by JH4 in liver at 6 hours was observed after 24 hours in kidney. We were able to recover the progerin-binding biotin-JH4 (labeled “07” in Figure 8D) in liver 6 hours after injection, indicating, as we expected, that JH4 could work in an in vivo system.

JH4 extends lifespan in the progerin mouse model. Next, we assessed the lifespan of Lmna+/G609G progeroid mice after JH4 injection. As shown in Figure 8E, the lifespan of JH4-treated progeroid mice was extended by more than 4 weeks compared with that of vehicle-treated mice. Although JH4 treatment did not fully overcome the short lifespan of these animals, considering the low concentration (10 mg/kg) and frequency (2 times/week) of administration, it appears to have a promising effect. In fact, JH4 also significantly extended the lifespan of Lmna+/G609G heterozygous mice (Figure 8F). Since biological effect of JH4 was dose-dependent, we injected 20 mg/kg JH4 into Lmna+/G609G progeroid mice. From this experiment, we found that 20 mg/kg JH4 could extend lifespan by as much as 26 weeks (Figure 8G). These results suggest that if JH4 can be retained at a higher concentration, lifespan could be more dramatically extended and that JH4 would be a strong therapeutic drug candidate for the treatment of HGPS.

Discussion

The aging process is complicated, and a full understanding of the molecular mechanisms controlling it is not likely to be realized in the near future. However, some basic clues are known from studying human progeria syndromes such as HGPS (39–41). Although HGPS is caused by progerin, a product of a point mutation in the LMNA gene, progerin is also expressed in normal aged cells as well as in cancers (14). Thus, understanding the pathological function of progerin is useful for the development of a therapeutic strategy to treat HGPS as well as for the prevention of aging.

In fact, over the past decade, the farnesylation of progerin has been targeted for drug development to treat HGPS. (24, 42). Because the farnesylated domain of progerin rigidly anchors it to the nuclear membrane, it may induce nuclear deformation. Blocking farnesylation by FTIs in HGPS cells restores nuclear morphology, cell proliferation, and heterochromatin organization. Moreover, treatment with FTIs in HGPS-like mouse models improves lifespan, growth, and BW and relieves premature aging symptoms such as bone defects (23). In particular, FTIs can extend the lifespan of Zmpste24−/− mice (24). However, a clinical trial of FTI did not produce promising results (43), indicating that other targets should be explored.

In this study, we found that the most important target of progerin is lamin A/C. Indeed, progerin shows strong binding affinity for lamin A/C but not lamin B (Figure 1E). On this basis, we found new chemicals that can block the interaction between progerin and lamin A/C through direct interaction with progerin (Figure 2B and Figure 3E). Since the chemical JH4 can bind selectively to progerin, there would be very minimal, nonspecific side effects. In our study, JH4 did not show an effect on the progerin-independent progeria model (Zmpste24−/− mice; Supplemental Figure 14C) or on mouse and monkey cell lines (data not shown). These results indicate that JH4 has potential use as a progerin-inhibitory drug.

Although JH4 did not fully overcome the short lifespan of the Lmna+/G609G mouse model, given the low dose and frequent injections of the compound, an optimized treatment strategy using JH4 could offer an effective therapy. Indeed, the same scheduled injection produced more obvious effects in Lmna+/G609G mice (Figure 8), and JH4 appeared to be excreted within 24 hours.

In summary, in this study, we have identified 3 compounds, JH1, JH4, and JH13, that efficiently block progerin–lamin A/C
binding and reverse or alleviate different senescence features characteristic of HGPS cells, including growth arrest, SA-β-gal accumulation, and nuclear aberrations. Moreover, we observed similarly favorable effects of JH chemicals on normal aged fibroblasts, which also express progerin. Indeed, JH4 suppressed SA-β-gal activity and increased the proliferation of these cells. Moreover, many genes altered by JH4 treatment were common between HGPS and aging cells. The fact that this compound also rescued several progeroid features of Lmna<sup>G609G/G609G</sup> mice and extended the lifespan of this HGPS mouse model represents a proof of principle for the in vivo relevance of blocking progerin–lamin A/C interaction as a new treatment strategy for HGPS and, eventually, for age-associated alterations involving nuclear envelope abnormalities.

**Methods**

**Animal experiments.** Progerin-heterozygous Lmna<sup>+/G609G</sup> mice were provided by Carlos López-Otín (Universidad de Oviedo, Asturias, Oviedo, Spain). Timed matings of heterozygous Lmna<sup>+/G609G</sup> and homozygous Lmna<sup>G609G/G609G</sup> males and females were conducted, and chemical was intraperitoneally injected for indicated weeks or months (Figure 8, E–G). All mice were maintained on outbred C57BL/6J backgrounds.

**Histology.** Following sacrifice at the end of the injection regimen, the indicated organs (foot pad, kidney, and heart) were isolated in PBS and fixed in 10% formaldehyde in PBS at 4°C for 6 to 12 hours. Tissue was dehydrated using ethanol (50%, 70%, 90%, 3 x 100%; 5 minutes each) and paraffin embedded for sectioning. Sections (5-μm-thick) were used for H&E staining.

**Chemical screening and chemical synthesis.** For chemical screening, an ELISA was established by modifying a previously described platform (44). Details on the synthetic methods used are provided in the Supplemental material.

**Cell culture and reagents.** Human fibroblast cells were obtained from the Coriell Cell Repositories. Human cancer cell lines (HCT116, A549, and HEK293), obtained from ATCC, were maintained in liquid medium containing 10% FBS and 1% antibiotics at 37°C. Nonhuman cell lines such as Vero (monkey), HICIC7 (mouse), MDCK (canine), and Mv1Lu (mink) were obtained from the Korean Cell Line Bank (KCLB, Seoul, Korea).

**Plasmids and transfection.** GFP-progerin and GFP-fused lamin A expression vectors were provided by T. Misteli (National Cancer Institute [NCI], Bethesda, Maryland, USA). GFP-lamin B1 and lamin C were provided by J. Lammendering (Brigham and Women’s Hospital/Harvard Medical School, Boston, Massachusetts, USA). Mutant forms of lamin A were gifts of F. Tesson (University of Ottawa, Ottawa, Ontario, Canada). The Myc-ARF vector and OST-LAMINA A50 vector were purchased from Addgene. Transfection was performed using jetPEI (Polyplus Transfection) following the manufacturer’s protocol.

**Recombinant proteins and GST pull-down assay.** For investigation of protein-protein interactions, recombinant proteins were generated. Recombinant lamin A N-terminal region (His-LMNA-N; aa residues 1-300) and middle region (His-LMNA-M; 301-564 aa) was cloned into His-tagged pPROEXHT. GST-fused recombinant lamin A/C-terminal region (GST-LMNA) and progerin C-terminal region (GST-progerin) were produced by PCR cloning 100 aa upstream of the termination codon through PCR. Full-length p14<sup>ARF</sup> was produced by PCR, cloned into the pGEX vector, and confirmed by DNA sequencing. These recombinant proteins were purified using a nickel column. For the binding assay, GST-bead-lamin A/C or progerin-C was incubated with lysate from 293 cells that had been transfected with recombinant lamin A N-terminal region, lamin A middle region, GFP-lamin A, lamin B or lamin C for 2 hours at room temperature. After washing twice with PBS and once with RIPA buffer (50 mM Tris, 150 mM NaCl, 1% NP-40, 0.5% deoxycholate, and 0.5% SDS), precipitated materials were collected and subjected to SDS-PAGE and Western blotting using anti-GFP, His, and GST Abs.

**Streptavidin-biotin-binding assay.** Biotin-conjugated JH4 was produced by chemical synthesis (see the Chemical Synthesis section in the Supplemental materials). To determine the location of JH4-biotin, cells were incubated with biotin or biotin-JH4 for the indicated durations (Figure 3) and fixed with 2% PFA. After permeabilization, blocking with BSA, and prereaction with H2O2 to eliminate endogenous HRP activity, cells were incubated with streptavidin-HRP (Sigma-Aldrich) and DAB solution (Vector Laboratories). To investigate the direct binding of JH4 and progerin, cells lysates, precleared by streptavidin-bead, were incubated with biotin-JH4 or biotin and streptavidin-bead, sequentially. The precipitated materials were subjected to SDS-PAGE and Western blot analysis.

**Microarray data.** The full data set is available in the NCBI’s Gene Expression Omnibus (GEO) database (GEO GSE84147; www.ncbi.nlm.gov/geo/query/acc.cgi?acc=GSE84147).

**Statistics.** All data are expressed as the mean ± SEM. Statistical significance was determined using a 2-tailed Student’s t test. For all experiments, a P value of less than 0.05 was considered statistically significant.

**Study approval.** All in vivo studies were performed at an Association for Assessment and Accreditation of Laboratory Animal Care-certified facility, in compliance with animal policies approved by Pusan National University (Busan, Korea) and the Universidad de Oviedo (Asturias, Oviedo, Spain).
