MST1-dependent vesicle trafficking regulates neutrophil transmigration through the vascular basement membrane

Angela R.M. Kurz, … , Sergio D. Catz, Markus Sperandio

Neutrophils need to penetrate the perivascular basement membrane for successful extravasation into inflamed tissue, but this process is incompletely understood. Recent findings have associated mammalian sterile 20–like kinase 1 (MST1) loss of function with a human primary immunodeficiency disorder, suggesting that MST1 may be involved in immune cell migration. Here, we have shown that MST1 is a critical regulator of neutrophil extravasation during inflammation. *Mst1*−/− neutrophils were unable to migrate into inflamed murine cremaster muscle venules, instead persisting between the endothelium and the basement membrane. *Mst1*−/− neutrophils also failed to extravasate from gastric submucosal vessels in a murine model of *Helicobacter pylori* infection. Mechanistically, we observed defective translocation of VLA-3, VLA-6, and neutrophil elastase from intracellular vesicles to the surface of *Mst1*−/− neutrophils, indicating that MST1 is required for this crucial step in neutrophil transmigration. Furthermore, we found that MST1 associates with the Rab27 effector protein synaptotagmin-like protein 1 (JFC1, encoded by *Sytl1* in mice), but not Munc13-4, thereby regulating the trafficking of Rab27-positive vesicles to the cellular membrane. Together, these findings highlight a role for MST1 in vesicle trafficking and extravasation in neutrophils, providing an additional mechanistic explanation for the severe immune defect observed in patients with MST1 deficiency.

Wiessner, Andreas Margraf, Dae-Sik Lim, Barbara Walzog, Steffen Dietzel, Markus Moser, Christoph Klein, Dietmar Vestweber, Rainer Haas, Sergio D. Catz, and Markus Sperandio

Neutrophils need to penetrate the perivascular basement membrane for successful extravasation into inflamed tissue, but this process is incompletely understood. Recent findings have associated mammalian sterile 20-like kinase 1 (MST1) loss of function with a human primary immunodeficiency disorder, suggesting that MST1 may be involved in immune cell migration. Here, we have shown that MST1 is a critical regulator of neutrophil extravasation during inflammation. MST1-deficient (Mst1−/−) neutrophils were unable to migrate into inflamed murine cremaster muscle venules, instead persisting between the endothelium and the basement membrane. Mst1−/− neutrophils also failed to extravasate from gastric submucosal vessels in a murine model of Helicobacter pylori infection. Mechanistically, we observed defective translocation of VLA-3, VLA-6, and neutrophil elastase from intracellular vesicles to the surface of Mst1−/− neutrophils, indicating that MST1 is required for this crucial step in neutrophil transmigration. Furthermore, we found that MST1 associates with the Rab27 effector protein synaptotagmin-like protein 1 (JFC1, encoded by Sytl1 in mice), but not Munc13-4, thereby regulating the trafficking of Rab27-positive vesicles to the cellular membrane. Together, these findings highlight a role for MST1 in vesicle trafficking and extravasation in neutrophils, providing an additional mechanistic explanation for the severe immune defect observed in patients with MST1 deficiency.

Introduction

Recruitment of neutrophils from the intravascular compartment to sites of inflammation is a fundamental process during the innate immune response. The process follows a well-defined cascade of events, including neutrophil capture and rolling, firm adhesion, crawling, extravasation, and migration into inflamed tissue (1). Although most of the recruitment steps have been thoroughly studied in the past (2), the precise mechanism of neutrophil transmigration across venular walls and penetration of the perivascular basement membrane (BM) remains elusive (3–6). Once neutrophils have migrated through the endothelial layer, they are primed for subsequent penetration of the endothelial BM (7–9) at sites that express low levels of laminin 511 (10–12) and potentially also low levels of collagen IV (13). So far, it is known that the surface expression of VLA-3 (integrin α3β1), also known as CD49c/CD29) (14) and VLA-6 (integrin α6β1, also known as CD49f/CD29) (15), 2 laminin-binding integrins on neutrophils, is required for migration into inflamed tissue. VLA-3 was shown to be necessary for neutrophil extravasation in TNF-α- and fMLP-induced transmigration in vivo (14, 16), while studies using blocking antibodies suggest a role for VLA-6 in IL-1β–dependent, but not TNF-α–dependent, neutrophil extravasation (15). Migration through the BM was described to be further accompanied by the surface expression of the serine protease neutrophil elastase (NE) (17), although experiments using NE-deficient mice in vivo could not confirm a role in the extravasation process (18). Since VLA-3, VLA-6, and NE are stored in intracellular vesicles (17, 19), they need to be translocated to the cell surface during transmigration. Rab27 GTPases are involved in vesicle trafficking in neutrophils (20). Rab27a has emerged as a central regulator of many neutrophil functions through its ability to regulate vesicle exocytosis (21). So far, 2 effector molecules, namely synaptotagmin-like protein 1 (JFC1, encoded by Sytl1 in mice) and Munc13-4 (UNC13D), have been identified as interacting with Rab27a in neutrophils (22–25).

Recently, 3 independent groups identified a novel human primary immunodeficiency disorder, caused by autosomal recessive loss-of-function mutation in serine/threonine protein kinase 4 (STK4), which encodes the mammalian sterile 20-like kinase 1
Figure 1. MST1 is dispensable for neutrophil adhesion in humans and mice, but critical for neutrophil extravasation into inflamed peritoneum. (A) MST1 and MST2 protein levels of WT and Mst1–/– neutrophils. GAPDH served as loading control (n = 3). (B) Differential blood counts of WT (n = 20) and Mst1–/– mice (n = 14) (scatter plot with mean, ***P < 0.001, 2-way ANOVA, Sidak’s multiple comparisons test). (C) Neutrophil adhesion efficiency (arbitrary units) in cremaster muscle venules of WT and Mst1–/– mice, 2 hours after intrascrotal injection of TNF-α (n = 5, mean ± SEM, NS, unpaired t test). (D) Number of adherent leukocytes per field of view (FOV) in microflow chambers coated with E-selectin, E-selectin/ICAM-1, or E-selectin/ICAM-1/CXCL1 (n = 3, mean ± SEM, NS, 2-way ANOVA, Sidak’s multiple comparisons test). (E) LFA-1 clustering of WT or Mst1–/– cells labeled with anti–LFA-1 antibody conjugated with Alexa 546 (fluorescence intensity scale). Whole blood was perfused through microflow chambers coated with E-selectin, ICAM-1, and CXCL1 (Supplemental Videos 1 and 2) (n = 3 mice, 1 representative picture is shown). Scale bar: 10 μm. (F) Number of adherent neutrophils per field of view from 2 patients with STK4 deficiency and their heterozygous parents was calculated over time in flow chambers coated with E-selectin/ICAM-1/CXCL8 (n = 2, chambers ≥2, mean ± SEM). (G) Total number of extravasated neutrophils in the peritoneal lavage 2 hours after i.p. injection of NaCl or TNF-α in WT and Mst1–/– mice (n = 5, scatter plot with mean, ***P < 0.001, 2-way ANOVA, Tukey’s multiple comparisons test).
(MST1), the mammalian homolog of the Drosophila melanogaster kinase Hippo. Children with STK4 deficiency display recurrent bacterial, viral, and fungal infections together with autoimmune disease. They also suffer from lymphopenia, which explains part of the clinical manifestations. However, their impaired response to acute bacterial infections also suggests a defect in myeloid cell function (26–28).

Studies using Mst1-deficient mice showed that the ubiquitously expressed serine/threonine kinase MST1 is involved in lymphocyte trafficking by controlling exocytosis and localization of the β2 integrin lymphocyte function-associated antigen-1 (LFA-1, also known as CD11a/CD18 or integrin αβ2) to the plasma membrane. MST1 associates via RAPL with the cytoplasmic tail of the α, subunit and leads to the translocation of LFA-1-containing vesicles in a DENND1C/Rab13-dependent manner (29). The absence of MST1 in lymphocytes leads to adhesion as well as migration defects, resulting in impaired lymphocyte trafficking and a decreased number of peripheral lymphocytes (30, 31). To investigate the role of MST1 for myeloid cell function, we evaluated neutrophil recruitment in Mst1–/– mice under in vivo and in vitro conditions. We show that MST1 is dispensable for LFA-1-dependent neutrophil adhesion in mice and humans. In contrast, MST1 is critical for the translocation of vesicles containing VLA-3, VLA-6, and NE to the neutrophil surface, by cooperating with the Rab27 effector protein JFC1. This translocation enables neutrophils to penetrate the BM and extravasate into the interstitial space. Hence, we identify MST1 deficiency as a neutrophil transmigration deficiency with a BM penetration defect due to the role of MST1 in vesicle trafficking.

Results

MST1 is dispensable for neutrophil adhesion but critical for extravasation. In the past, conflicting results on the expression of MST1 in mouse neutrophils were published (32). Therefore, we first confirmed the expression of MST1 in neutrophils from WT and the absence of MST1 in Mst1–/– neutrophils (Figure 1A). Notably, we did not detect any MST2 expression either in WT or in Mst1–/– neutrophils (Figure 1A and Supplamental Figure 1A; supplemental material available online with this article; doi:10.1172/JCI87043DS1). Next, we determined differential cell counts of peripheral blood, and our results are in accordance with previously published data (33) showing decreased numbers of lymphocytes in Mst1–/– mice compared with WT mice (Figure 1B). In contrast, neutrophil counts were not significantly altered in Mst1–/– mice compared with WT mice. Since lack of MST1 enhanced susceptibility to apoptosis in T cells (31, 34) and in neutrophils from STK4-deficient patients (26), we evaluated whether MST1 deficiency influences apoptosis of murine neutrophils. We found that neutrophils from WT and Mst1–/– mice showed no significant difference in the viability and apoptosis rate in vitro and in vivo (Supplemental Figure 1, B and C).

Previous studies had shown that MST1 is crucial for T cell adhesion dependent on the β2 integrin LFA-1 (30). To test whether LFA-1-dependent adhesion is also affected in neutrophils lacking MST1, we compared neutrophil adhesion efficiency in TNF-α-stimulated cremaster muscle venules of WT and Mst1–/– mice using intravital microscopy. Unexpectedly, we observed no difference in neutrophil adhesion efficiency between WT and Mst1–/– mice (Figure 1C). In addition, neutrophil rolling flux fraction and neutrophil rolling velocity, which is regulated by LFA-1, were not altered in Mst1–/– mice compared with WT mice (Supplemental Figure 1, D and E). We then performed ex vivo flow chamber assays using glass capillaries coated with various combinations of adhesion molecules and found no difference in the number of adherent leukocytes (Figure 1D). Furthermore, Mst1–/– neutrophils displayed proper LFA-1 reorganization and accumulation at the uropod during postarrest modifications as observed in flow chambers using confocal microscopy (Figure 1E and Supplemental Videos 1 and 2). In addition, CXCL1-dependent LFA-1 activation in a soluble ICAM-1 binding assay was similar between neutrophils isolated from WT and Mst1–/– mice (Supplemental Figure 1, F and G). Neutrophil surface expression of LFA-1, Mac-1, CXCR2, CD44, PSGL1, and CD62L was similar in WT and Mst1–/– mice (Supplemental Figure 1H).

Next, we investigated adhesion of neutrophils from 2 human patients with STK4 (also known as MST1) deficiency and their heterozygous parents (26). For this approach, we determined the number of adherent neutrophils per field of view in flow chambers coated with E-selectin/ICAM-1/CXCL8. The number of adherent neutrophils per field of view of STK4–/– patients was similar to adhesion observed for chambers perfused with neutrophils from their heterozygous (STK4+/–) parents (Figure 1F).

We then went on and asked whether MST1 deficiency could have any impact on neutrophil extravasation in a TNF-α-induced peritonitis model. In WT mice, i.p. injection of TNF-α dramatically increased the number of neutrophils in the peritoneum compared with NaCl control injection. In contrast, neutrophils from Mst1–/– mice failed to transmigrate into the peritoneal cavity within 2 hours of TNF-α stimulation (Figure 1G).

Taken together, these in vitro and in vivo results demonstrate that, in contrast to T cells, MST1 is dispensable for LFA-1 activation and clustering in neutrophils. Hence, neutrophil adhesion is unaffected in Mst1–/– mice as well as in patients with STK4 deficiency. However, we could detect a massive decrease in the number of extravasated neutrophils in the peritoneal lavage of Mst1–/– mice compared with WT mice in the TNF-α-induced peritonitis model, suggesting a neutrophil recruitment defect downstream of intravascular adhesion.

Loss of MST1 in neutrophils results in decreased transmigration in vivo. Using multiphoton laser scanning microscopy, we next investigated neutrophil transmigration 180–240 minutes after intrascrotal injection of TNF-α, together with a nonblocking antibody against PECAM-1 (35), into Lyz2GFP (36) and Mst1–/– × Lyz2GFP mice, where neutrophils are endogenously labeled with EGFP. We observed an increasing number of neutrophils in Lyz2GFP mice crossing postcapillary venules and migrating into the inflamed tissue (Figure 2A, top panel, and Supplemental Video 3). In contrast, neutrophils from Mst1–/– × Lyz2GFP mice remained close to the abluminal part of the vessel wall (Figure 2A, bottom panel, and Supplemental Video 4). We then determined the duration of neutrophil transmigration into tissue and observed that transmigration of Lyz2GFP mice required 7.5 ± 0.8 minutes (median ± SEM), which is similar to the time reported by others (35). In contrast, most neutrophils of Mst1–/– × Lyz2GFP mice failed to transmigrate into tissue...
Figure 2. Mst1−/− neutrophils fail to transmigrate into inflamed tissue. Neutrophils (green) and microvasculature (red, anti–PECAM-1) of TNF-α-stimulated mouse cremaster muscle. (A) Neutrophil transmigration in Lyz2GFP (top panels) and Lyz2GFP × Mst1−/− mice (bottom panels, white arrows) at 180 minutes, 210 minutes, and 240 minutes after intrascrotal injection of TNF-α. Images were obtained using intravital multiphoton microscopy (n = 5). Scale bar: 30 μm. (B) Transmigration time of Lyz2GFP and Lyz2GFP × Mst1−/− neutrophils. Cutoff was set at 20 minutes (n = 5 mice, scatter plot with median of >50 analyzed transmigration events per group, ***P < 0.001, Mann-Whitney test). (C) 3D reconstruction of neutrophil (green) transmigration with subendothelial accumulation of Lyz2GFP × Mst1−/− neutrophils (white circles) and complete extravasation of Lyz2GFP neutrophils. Scale bar: 20 μm. (D) Representative images of swarming neutrophils (green) and the microvasculature (PECAM-1, red) in the cremaster muscle of Lyz2GFP and Lyz2GFP × Mst1−/− mice after induction of a laser injury (white squares). Scale bar: 50 μm. (E) Intensity profile of the GFP signal relative to background (rel to bg) in Lyz2GFP and Lyz2GFP × Mst1−/− mice at the site of laser injury (n = 5, mean ± SEM, ***P < 0.001 after 16 minutes, 2-way ANOVA, Sidak’s multiple comparisons test).
Interestingly, neutrophils deficient in MST1 remained at the abluminal site of venules and were unable to interstitially migrate to the site of laser injury (Figure 2, D and E, and Supplemental Videos 5 and 6). However, absence of interstitial migration was not due to an intrinsic migration defect of Mst1–/– neutrophils, as migration of bone marrow–derived neutrophils to fMLP or CXCL1 in a 3D collagen gel assay was similar to that of WT neutrophils (Supplemental Figure 2, A and B).

within the 20 minutes of observation (20 ± 0.8 minutes, median ± SEM) (Figure 2B) and accumulated at the abluminal site of postcapillary venules (Figure 2C).

To test whether further inflammatory stimulation could induce migration into the interstitial matrix, a laser injury near postcapillary venules was set 3 hours after TNF-α stimulation. Neutrophils of Lyz2GFP–/– mice swarmed and accumulated at the site of laser injury within 30 minutes, as described by Lämmermann et al. (37). Interestingly, neutrophils deficient in MST1 remained at the abluminal site of venules and were unable to interstitially migrate to the site of laser injury (Figure 2, D and E, and Supplemental Videos 5 and 6). However, absence of interstitial migration was not due to an intrinsic migration defect of Mst1–/– neutrophils, as migration of bone marrow–derived neutrophils to fMLP or CXCL1 in a 3D collagen gel assay was similar to that of WT neutrophils (Supplemental Figure 2, A and B).

MST1-deficient neutrophils fail to transmigrate to the site of infection in a Helicobacter pylori mouse infection model. Next, we evaluated the role of MST1 in a murine Helicobacter pylori infection model. Previous work had shown that neutrophils play an important role in the pathogenesis of H. pylori infection (38). The bacterium induces a strong inflammatory response in the gastric mucosa, which is dependent on the H. pylori neutrophil-activating protein (HP-NAP). Furthermore, proinflammatory cytokines such as CXCL8 are secreted during the inflammatory process, recruiting additional neutrophils and monocytes to the site of inflammation (39).

We infected WT and Mst1–/– mice with H. pylori orogastrically and sacrificed the mice 3 months later. As reported earlier (40), in WT mice, the majority of infiltrated neutrophils were found in the antrum region of the stomach (Figure 3A, top panel). In contrast, we only detected a very small number of neutrophils in the gastric epithelium of the antrum of Mst1–/– mice (Figure 3A, bottom panel), demonstrating reduced neutrophil extravasation (Figure 3B). In line with this, the number of CFU of H. pylori in the antrum showed a significant increase in Mst1–/– mice compared with WT mice (Figure 3C), indicating a more successful colonization.

Finally, we immunostained tissue sections from the lower part of the mucosa, where neutrophils extravasate from postcapillary venules (Figure 3D). We did not observe any difference in the number of total neutrophils per field of view between WT and Mst1–/– mice (Figure 3E). However, in WT mice neutrophils migrated from venules into the inflamed tissue, while, as expected, neutrophils from Mst1–/– mice remained near the vessel wall (Figure 3F). Thus, MST1 is required for proper neutrophil extravasation from the submucosal vasculature into tissue during H. pylori infection.

MST1 is essential for neutrophils to penetrate the BM. Next, we focused on the capacity of Mst1–/– neutrophils to penetrate the perivascular BM. To this end, we performed whole-mount stainings of TNF-α-stimulated cremaster muscle whole mounts from WT and Mst1–/– mice for laminin α5 (white, BM), ESAM1 (red, endothelial junctions), and MRPI4 (green, neutrophils) (n = 3). Scale bar: 20 μm. (B) 3D reconstruction and illustration of a vessel cross section demonstrating the classification of transmigrating neutrophils respective to their position. Position I, neutrophils in intimate contact with the endothelium; position II, neutrophils between the endothelium and the BM; position III, fully transmigrated neutrophils. Scale bar: 10 μm. (C) Distribution pattern of transmigrating neutrophils respective to their positions (positions I–III) in WT and Mst1–/– mice (n = 45 analyzed vessels from 5 mice per group, scatter plot with mean of >25 analyzed vessels per group, **P < 0.001, ***P > 0.001, twoway ANOVA, Sidak’s multiple comparisons test). (D–F) Neutrophil transmigration in a Transwell assay with or without CXCL1 through filters coated with BSA (control), laminin 1 (LN-1), or LN-1, PECAM-1, and ICAM-1 (LN-1/P/I) (n = 3 mice, triplicate measurements were performed, mean ± SEM, **P < 0.001, 2-way ANOVA, Sidak’s multiple comparisons test) (D); with or without CXCL1 through an endothelial monolayer of 1G11 cells (n = 3 mice, triplicate measurements were performed, mean ± SEM, ***P < 0.001, 2-way ANOVA, Sidak’s multiple comparisons test) (E); and to HBSS, 10 ng/ml and 100 ng/ml CXCL1 (n = 3 mice, duplicate measurements were performed, mean ± SEM, 2-way ANOVA, Sidak’s multiple comparisons test) (F).

and TNF-α–stimulated cremaster muscle whole mounts from WT and Mst1–/– mice. In unstimulated venules of WT mice we were unable to detect any NE activity, while 2 hours after TNF-α stimulation NE activity could be observed (Figure 5J). TNF-α–stimulated venules from Mst1–/– mice showed decreased NE activity as compared with those from WT mice (Figure 5J). Importantly, the number of adherent cells was similar in WT and Mst1–/– mice (Supplemental Figure 4B).

In order to confirm that blocking VLA-3, VLA-6, and NE affects neutrophil extravasation in vivo we used the TNF-α–induced peritonitis model. WT mice treated with the VLA-3–blocking peptide LXY2, the α6–blocking mAb GoH3, and the NE inhibitor GW311616A; or solvent alone, control peptide, and isotype-matched control mAb (n = 6, mean ± SEM, **P < 0.01, unpaired t test).

Finally, we examined the role of Rab27a and its 2 effector molecules, JFC1 and Munc13-4, in neutrophils. Rab27a was shown to be required for LFA-1–dependent neutrophil adhesion in mice and has been shown to influence many neutrophil functions through its ability to regulate vesicle exocytosis (21, 42). Therefore, we investigated Rab27a translocation to the plasma membrane in response to PECA-1/ICAM-1/CXCL1 stimulation. Rab27a displayed an intracellular localization in WT and Mst1–/– neutrophils (Figure 6A) and a decreased number of transmigrated neutrophils compared with control WT mice (Figure 5K).

Taken together, these in vitro and in vivo results demonstrate that Mst1 is indispensable for efficient translocation of VLA-3, VLA-6, and NE to the surface of neutrophils.

MST1 regulates vesicle trafficking together with JFC1, a Rab27 effector molecule. Rab27a is a central regulator of vesicle trafficking in neutrophils and has been shown to influence many neutrophil functions through its ability to regulate vesicle exocytosis (21, 42). Therefore, we investigated Rab27a translocation to the plasma membrane in response to PECA-1/ICAM-1/CXCL1 stimulation. Rab27a displayed an intracellular localization in WT and Mst1–/– neutrophils when seeded on BSA (Figure 6A and Supplemental Figure 4A). In WT neutrophils, PECA-1/ICAM-1/CXCL1 coating induced the translocation of Rab27a to the plasma membrane (Figure 6, A and B) and led to ring formation of Rab27a in most analyzed WT neutrophils (Figure 6C). In contrast, neutrophils derived from Mst1–/– mice failed to translocate Rab27a to the plasma membrane in response to PECA-1/ICAM-1/CXCL1 stimulation (Figure 6, A–C). Importantly, total protein levels of Rab27a were similar between WT and Mst1–/– neutrophils (Supplemental Figure 4B).

Next, we investigated whether Mst1 itself translocates to the plasma membrane upon ICAM-1/PECA-1/CXCL1 stimulation. Mst1 displayed intracellular localization in WT neutrophils seeded on BSA (Figure 6, D–F). In response to ICAM-1/PECA-1/CXCL1 stimulation, Mst1 localized together with Rab27a at the plasma membrane (Figure 6, D–F).

Finally, we examined the role of Rab27a and its 2 effector molecules, JFC1 and Munc13-4 (22–25), during VLA-3 and VLA-6 translocation. To do this, we investigated the mobilization of VLA-3 and VLA-6 in response to PECA-1/ICAM-1/CXCL1 in WT, Rab27a–/– (Rab27a knockout), Syt1–/– (JFC1 knockout), and Munc13-4–/– (Munc13-4 knockout) neutrophils in WT, Rab27a+/+, and Munc13-4+/+ neutrophils, PECA-1/ICAM-1/CXCL1 coating induced the translocation of VLA-3 to the plasma membrane. In contrast, neutrophils derived from Syt1–/– mice showed decreased translocation of VLA-3 (Figure 6G). Furthermore, translocation of VLA-6 was decreased in neutrophils from Syt1–/– mice compared with neutrophils of WT and Rab27a+/+ mice. Interestingly, neutrophils from Munc13-4–/– mice showed an increased translocation of VLA-6 compared with WT neutrophils (Figure 6H).

Next, we used a continuous sucrose gradient and demonstrated that Rab27a and Mst1 are present in the same low-density granule fraction of human neutrophils (Figure 6I), suggesting that the interaction of these proteins contributes to the effective transport of VLA-3– and VLA-6–containing vesicles to the neutrophil surface.

Taken together, our results show that Mst1 and Rab27a are present in, and are located in the same subpopulation of, neutrophil granules. Furthermore, we provide evidence that Mst1 regulates PECA-1/ICAM-1/CXCL1–stimulated trafficking of vesicles containing VLA-3 and VLA-6 to the neutrophil surface via cooperation with the Rab27 effector protein JFC1, but not Munc13-4.

Discussion

In this study, we identify the serine/threonine kinase MST1 as the first signaling molecule indispensable for neutrophil BM penetration into inflamed tissue.

Originally, MST1 (mamalian homolog of the Drosophila Hippo protein) was identified in D. melanogaster as the central constituent of the Hippo pathway, controlling organ size and proliferation. Recently, MST1 has attracted more attention due to its role in cancer development (43) and the discovery that a mutation in human STK4 (MST1) leads to a primary immune deficiency. Patients with a deficiency in STK4 present with recurring bacterial, fungal, and viral infections, and display lymphopenia and intermittent neutropenia (26–28). Using Mst1–/– mice, MST1 was shown to be required for LFA-1–dependent T cell trafficking (31) by regulating the transport and distribution of LFA-1–containing vesicles to the plasma membrane and subsequent LFA-1 clustering and adhesion of T cells (30).

We demonstrate that — in contrast to T cells — MST1 is dispensable for LFA-1–dependent neutrophil adhesion in mice and humans. Neutrophils from Mst1–/– mice showed no defect in LFA-1 activation. In addition, clustering of LFA-1 as well as static adhesion on ICAM-1–coated surfaces was not altered in Mst1–/– neutrophils compared with WT neutrophils. Murine Mst1–/– neutrophils as well as neutrophils derived from patients with STK4 deficiency adhered to E-selectin/ICAM-1/CXCL1–coated flow chambers.
to the same extent as WT controls or the patients’ heterozygote parents, respectively. These results suggest that different mechanisms of LFA-1 regulation/activation exist between lymphocytes and neutrophils. This may be supported by data from Fabbrì et al., reporting that Rab11 is required for the trafficking of LFA-1-containing vesicles in neutrophils (44). In T cells, Rab13 is responsible for this step (29).

Although Mst1−/− neutrophils showed no defective adhesion in our studies, they failed to extravasate into the peritoneal cavity. In TNF-α-stimulated cremaster muscles, Mst1−/− neutrophils remained in close contact with the abluminal side of the vessel. Even after additional stimulation by induction of a laser injury next to the vessel, Mst1−/− neutrophils persisted adjacent to the vessel wall and failed to migrate to the site of injury. After crossing the endothelial cell layer, neutrophils have to penetrate the underlying BM (3, 5, 13). The BM of postcapillary venules is mainly composed of laminin 411 (α4β1γ1 laminin subunit), laminin 511 (α5β1γ1 laminin subunit), and type IV collagen (5). Although many studies have been performed on leukocyte adhesion and transendothelial migration, the mechanism by which neutrophils penetrate the BM is still poorly understood (3, 4).

Previous studies showed that genetic, antibody- or inhibitor-mediated blockade of PECAM-1 (17), VLA-3 (14, 16), VLA-6 (15, 17, 45), or NE (17) leads to an arrest of infiltrating neutrophils between the endothelial layer and the underlying BM. Extravasating neutrophils need to interact with ICAM-1 and PECAM-1 to induce the mobilization of vesicles containing VLA-6 and NE. This mobilization translates VLA-6 and NE to the cellular surface, a prerequisite to pass the BM (17, 45). We found that Mst1 is essential for the exocytosis of VLA-3, VLA-6, and NE, as neutrophils from Mst1−/− mice failed to translocate these proteins to the cell surface upon stimulation with PECAM-1/ICAM-1/CXCL1. In contrast to WT neutrophils, neutrophils from Mst1−/− mice failed to pass through a PECAM-1, ICAM-1, and laminin-coated transwell filter in an in vitro transmigration assay. Furthermore, blockade of VLA-3, VLA-6, and NE decreased neutrophil extravasation into the peritoneal cavity in WT mice in response to TNF-α.

As MST1 influences LFA-1 clustering in T cells by regulating a protein that shares 71% homology with Rab27a at the amino acid level (47) and is known to mediate many common trafficking mechanisms through interaction with Rab27-specific effectors (48, 49). In order to better understand the mechanism underlying the regulation of VLA-3 and VLA-6 mobilization and to establish a definite role for Rab27a-dependent mechanisms in this process, we next studied neutrophils from mice lacking the expression of the Rab27 effector JFC1 (50) or Munc13-4 (51). Two molecules known to bind to and modulate processes regulated by both Rab27a (50, 51) and Rab27b (48, 49), a protein that shares 71% homology with Rab27a at the amino acid level (47). Rab27b has functional redundancy with Rab27a (47) and is known to mediate many common trafficking mechanisms through interaction with Rab27-specific effectors (48, 49). In order to better understand the mechanism underlying the regulation of VLA-3 and VLA-6 mobilization and to establish a

In conclusion, we demonstrate that the serine/threonine kinase MST1 is indispensable for neutrophil penetration of the vascular BM by regulating the mobilization of VLA-3, VLA-6, and NE from intracellular vesicles to the plasma membrane. These findings elucidate the importance of MST1 for early innate immune responses. They also show that this neutrophil transmigration defect contributes to the phenotype of recurring infections found in patients suffering from STK4 immune deficiency.
Methods

**Western blot.** Isolated bone marrow–derived neutrophils (EasySep mouse neutrophil enrichment kit; STEMCELL Technologies) were incubated in lysis buffer (150 mM NaCl, 1% Triton X-100 [Appli-chem], 0.5% Na deoxycholate [Sigma-Aldrich], 50 mM Tris-HCl pH 7.3 [Merck], 2 mM EDTA [Merck]) supplemented with protease [Roche] and phosphatase inhibitors [Sigma-Aldrich],) homogenized in Laemmli sample buffer, and boiled for 5 minutes. Proteins were resolved by SDS-PAGE and then electrophoretically transferred onto PVDF membranes, which were subsequently incubated with antibodies. The following antibodies were used: rabbit anti-MST1 antibody (Upstate), rabbit anti-MST2 antibody (Cell Signaling Technology), rabbit anti-NE antibody (Abcam), mouse anti-VLA-3 antibody (42/ CD49c; BD), rabbit anti-VLA-6 antibody (Thermo Scientific), sheep anti-Rab27a (R&D Systems), mouse anti-GAPDH antibody (Calbiochem), goat anti-mouse–HRP, goat anti-rabbit–HRP, or donkey anti-sheep–HRP (Jackson ImmunoResearch). Bound antibodies were detected using ECL (Millipore Corp.).

**Intravital microscopy of TNF-α-stimulated mouse cremaster muscle venules.** Intravital microscopy of mouse cremaster muscle venules was performed in WT and Mst1−/− mice, as previously described (52). Briefly, 2 hours after intracranial injection of TNF-α (R&D Systems; 500 ng/mouse) a carotid artery catheter was placed for blood sampling (ProCyte Dx; IDEXX Laboratories). Thereafter, the cremaster muscle was exteriorized, and rolling flux (rolling cells/ min divided by total neutrophil flux), rolling velocity, and leukocyte adhesion efficiency (number of adherent cells/mm divided by the systemic neutrophil count) were determined by intravital microscopy (BX51WI microscope, water immersion objective ×40, 0.80 NA, Olympus; CCD camera, CF8/1, Kappa). Postcapillary venules ranged from 20 to 40 μm in diameter.

**Murine ex vivo flow chamber system and LFA-1 clustering.** To investigate adhesion under flow conditions, we used a previously described flow chamber system (53). Glass capillaries (Rectangle Borosilicate Capillaries, 0.04 × 0.40 mm inner diameter; VitroCom) were coated with E-selectin (R&D Systems; 20 μg/ml), ICAM-1 (R&D Systems; 15 μg/ml), and/or CXCL1 (PeproTech; 15 μg/ml). Flow chambers were autopерфused with whole blood from WT or Mst1−/− mice via a carotid artery catheter. One representative field of view was recorded by intravital microscopy (water immersion objective ×20, 0.95 NA; Olympus).

In order to investigate LFA-1 clustering during neutrophil adhesion under flow conditions, flow chambers were perfused (2 μl/min) with whole blood from WT or Mst1−/− mice, incubated with rat anti-LFA-1 Alexa Fluor 546 antibody (2D7; BioLegend). Adherent cells were imaged using confocal microscopy (Leica SP5 system, ×63, 1.4 NA oil objective; Leica Microsystems).

**Human flow chamber system.** In order to investigate adhesion of human neutrophils under flow conditions, we used a previously described flow chamber system (54). Glass capillaries (Rectangle Borosilicate Capillaries, 0.2 × 2 mm inner diameter; VitroCom) were coated with combinations of E-selectin (R&D Systems; 5 μg/ml), ICAM-1 (R&D Systems; 4 μg/ml), and CXCL8 (PeproTech; 5 μg/ml). Flow chambers were perfused (2 dyn/cm²) with Ficol purified neutrophils (2 × 10⁶/ml) from parents (STK4±/−) or STK4+/- patients.

**Neutrophil viability.** Isolated neutrophils were cultured in HBSS buffer (containing 0.1% glucose, 1 mM CaCl₂, and MgCl₂, 0.25% BSA [GE Healthcare], and 10 mM HEPES [Sigma-Aldrich] pH 7.4) for 0, 24, 48, and 72 hours. Viability and apoptosis rate of Ly6G+ neutrophils were evaluated using TMRE (tetramethylrhodamine) and TO-PRO3 iodide (Invitrogen), respectively, and assessed by flow cytometry.

**Viability of neutrophils within the cremaster muscle.** To evaluate the viability of neutrophils within the whole cremaster muscle, TNF-α (500 ng/mouse) was injected into the scrotum of WT and Mst1−/− mice. Two hours later, the cremaster muscle was exteriorized, dissected, and digested with Liberase (0.25 mg/ml; Roche) for 1 hour at 37°C. Neutrophils were stained using rat anti-Ly6G antibody and TO-PRO3 and analyzed using flow cytometry.

**Surface expression of LFA-1, Mac-1, CXCR2, CD44, PSGL1, and CD62L.** Surface expression of α₅ (LFA-1, CD11a–allophycocyanin, M17/4; eBioscience), α₆ (Mac-1, CD11b–Brilliant Violet 570, M1/70; BioLegend), CXCR2 (CD182–allophycocyanin, 242216; R&D Systems), CD44 (CD44–Brilliant Violet 570, IM7; BioLegend), PSGL1 (CD162–phycocerythrin, 2PH1; Pharmingen), and L-selectin (CD62L–FITC, MEL-14; BioLegend) of bone marrow–derived Ly6G+ (Ly6G–Pacific Blue, IA8; BioLegend) neutrophils from WT and Mst1−/− mice was compared using a Beckman Coulter Galios flow cytometer and analyzed using Kalzu Flow Analysis Software (Beckman Coulter).

**Soluble ICAM-1 binding assay.** Soluble ICAM-1 binding assay was performed as described previously (52). Briefly, bone marrow–derived neutrophils were isolated from WT and Mst1−/− mice using a Percoll gradient (Sigma-Aldrich). Cells were suspended in HBSS buffer. Cells were stimulated with 100 ng/ml rmCXCL1 (PeproTech) or an equal volume of HBSS buffer, in the presence of rmICAM-1 (ICAM-1 hFc chimera; R&D Systems; 20 μg/ml), goat anti-human Fcγ–biotin (polyclonal; eBioscience), and streptavidin–PerCP-Cy5.5 (eBioscience), for 3 minutes at 37°C. Cells were fixed (FACS Lysing Solution; BD), stained with rat anti-mouse Ly6G–Pacific Blue antibody (IA8; BioLegend), and measured using a flow cytometer.

**TNF-α-induced neutrophil extravasation into the peritoneal cavity.** WT and Mst1−/− mice were injected i.p. with 0.9% NaCl (control) or TNF-α (rmTNF-α; R&D Systems; 2 μg/mouse). Mice were sacrificed 2 hours later, and peritoneal lavage was performed, cells were collected, and the number of extravasated neutrophils was evaluated using rat anti-Ly6G antibody (IA8; BioLegend), Flow-Count Fluospheres (Beckman Coulter), and flow cytometry. In a second set of experiments, WT mice were pretreated for 24 hours with the NE inhibitor GW311616A (BOC Sciences; 2mg/kg, orally) (55), followed by i.v. injection of the VLA-3–blocking peptide LXY2 (Bachem; H–cyco- [D–CyS–D–Asp–Gly–Tyr–(3–NO₂)–Gly–Pro–OH–Asn–D–Cys]–NH₂, 88 μg) (16) and the mAb against α₅ integrin (GoH3; BioLegend; 3 mg/kg) (17) 15 minutes before i.p. administration of TNF-α (2 μg/mouse). Control mice were pretreated for 24 hours with solvent, followed by i.v. injection of the control peptide (Bachem; H–Gly–Arg–Gly–Glu–Ser–OH, 88 μg) and isotype-matched control mAb (BioLegend; 3 mg/kg) 15 minutes before i.p. administration of TNF-α (2 μg/mouse). Two hours later, the number of extravasated neutrophils was evaluated using flow cytometry.

**Multiphoton microscopy of the mouse cremaster muscle.** Extravasation of neutrophils into inflamed mouse cremaster muscle of Lyz2GFP and Lyz2GFP × Mst1−/− mice was investigated by multiphoton microscopy. Briefly, TNF-α (R&D Systems; 500 ng/mouse) and a rat anti-PECAM-1 antibody Alexa Fluor 546 (390; BioLegend; 3 μg) were injected into the scrotum of mice. One hour later, the cremaster muscle was prepared for intravital multiphoton microscopy. Z-stacks were captured using a TrimScope (LaVision Bio Tec [ref. 56], upgraded with
Hamamatsu H7422A-40 high-sensitivity GaAsP photomultipliers; Olympus XULMPlanFI, ×20, 0.95 W objective, 810 nm excitation, ultrasmall port 525/30, 580/60). Images (966 × 966 pixels, 300 × 300 μm, step size 4 μm) were acquired at intervals of 30 seconds. After acquisition, images were processed and analyzed using Imaris 7 (Bitplane). Transmigration time was defined from the point when the cells started to transmigrate (excluding intraluminal crawling) until they completely detached from the abluminal vascular wall.

* Laser-induced injury using multiphoton microscopy in the mouse cremaster muscle. A laser injury using high laser power by scanning of an area of 50 × 50 μm 121 times in the center of 500 × 500 μm was set, 3 hours after intrascrotal injection of rmTNF-α and anti-PECAM-1-Alexa Fluor 546 antibody. Images were acquired for 30 minutes as described above. The GFP intensity, which is proportional to the number of neutrophils at the site of injury, was analyzed using Fiji software (57).

* Chemotaxis assay for neutrophils in 3D collagen gels. 3D chemotaxis was performed according to the manufacturer’s instructions (Ibidi). Briefly, bone marrow–derived neutrophils from WT and Mst1–/– mice were isolated using a Percoll gradient, and 3 × 106 cells were seeded together with collagen I into a channel of Ibidi μ-Slides Chemotaxis10. After 5 minutes of incubation at 37°C, the reservoirs were filled with either complete HBSS buffer alone or rmCXCL1 (PeproTech; 100 ng/ml) or fMLP (Sigma-Aldrich; 10 μM). Images were acquired every 4 seconds for 30 minutes at 37°C using an Axiovert 200M microscope. Images were analyzed using Fiji software.

* H. pylori infection model. WT or Mst1+/- mice were infected with the H. pylori strain PSM1swt oregastrically 3 times with 10⁸ bacteria or sterile Brucella Broth (BD) alone as a control. Animals were sacrificed after 6 weeks or 3 months. Stomachs were opened, washed with PBS, and divided into 2 equal halves. One half was homogenized, and appropriate dilutions were spread on selective serum plates (Difco GC agar [BD] with horse serum [80 ml/l], IsoVitaleX [10 ml/l; BD, Germany], nalidixic acid [5 g/l], bacitracin [50 g/l], and Dent [Oxoid]). The number of CFU was calculated per gram of gastric tissue. The other half of the stomach was fixed in Tissue-Tek OCT Compound (Sakura), stained with a primary rat anti-Ly6G antibody (BD Pharmingen), and detected using a goat anti-rat-Alexa Fluor 555 antibody (Invitrogen) together with DAPI (Sigma-Aldrich). Images were obtained using an Olympus fluorescence microscope (∼10, 0.40 NA dry objective). In a second set of experiments, the sections were stained with a rat anti-PECAM-1-Alexa Fluor 488 antibody (clone 390; BioLegend) together with a goat anti-Ly6G antibody (BD Pharmingen) detected with a goat anti-rat-Alexa Fluor 555 antibody (Invitrogen). DAPI was used for nuclear staining. Sections were imaged by confocal microscopy (Leica SP5 system, ×40, 1.25 NA oil objective). The number of neutrophils was evaluated using Velocity software.

* Analysis of neutrophil extravasation. TNF-α (R&D Systems; 500 ng/mouse) was applied to the scrotum of WT and Mst1+/- mice. After 2 hours the cremaster muscle was dissected and fixed with 4% paraformaldehyde for 1 hour, permeabilized and blocked for 2 hours in 0.5% Triton X-100/2% ovalbumin/PBS, and incubated with rat anti-laminin α5 antibody 4G6 (58), rabbit anti-ESAM1 antibody (9), and goat anti-MRP14 antibody (S100A9; R&D Systems) overnight in 2% ovalbumin/PBS at room temperature. After labeling with secondary antibodies (donkey anti-rat-Alexa Fluor 488, donkey anti-goat-Alexa Fluor 568, donkey anti-rabbit-Alexa Fluor 647; Invitrogen) in 1% ovalbumin/PBS for 5 hours at room temperature, the tissue was embedded on glass slides in Dako Fluorescence Mounting Medium. Images were acquired using a confocal microscope (Zeiss LSM 780, LSM 510) and analyzed by Imaris software.

* Transwell assay. HBSS buffer and 10 ng/ml or 100 ng/ml CXCL1 were used as chemoattractant in the Transwell system (5-μm pore size). Isolated bone marrow neutrophils (EasySep mouse neutrophil enrichment kit; STEMCELL Technologies) were applied and allowed to migrate for 45 minutes at 37°C. Numbers of transmigrated neutrophils were evaluated using rat anti-Ly6G antibody (IAB; BioLegend), Flow-Count Fluorospheres, and flow cytometry. In a second set of experiments, Transwells (3-μm pore size) were additionally coated with laminin 1 (Life Technologies; 15 μg/ml) or 2% BSA (GE Healthcare) as a control at 4°C overnight. Laminin was additionally coated with PECAM-1 (R&D Systems; 2 μg/ml) and ICAM-1 (R&D Systems; 8 μg/ml) for 2 hours at 37°C. Using HBSS buffer alone (control) or HBSS buffer with 1 ng/ml CXCL1 as chemoattractant, isolated bone marrow neutrophils (2 × 10⁶ cells per well) were allowed to migrate for 3 hours at 37°C (17). Numbers of transmigrated neutrophils were evaluated using rat anti-Ly6G antibody, Flow-Count Fluorospheres, and flow cytometry. In a third set of experiments, murine endothelial 1G11 cells (provided by Annunciata Vecchi, Humanitas Research Hospital, Milan, Italy) were seeded on Transwell inserts (5-μm pore size). Either HBSS buffer alone or HBSS buffer containing 100 ng/ml CXCL1 was added to the lower compartments. After 30 minutes of equilibration, isolated bone marrow neutrophils (2 × 10⁶ cells per well) were allowed to migrate for 1 hour at 37°C. Numbers of transmigrated cells were evaluated using rat anti-Ly6G antibody and Flow-Count Fluorospheres with flow cytometry.

* Mobilization of VLA-3, VLA-6, NE, MST1, and Rab27a in mouse neutrophils. Mobilization of NE, αi VLA-3, also known as CD49c, and αi VLA-6, also known as CD49f) on PECAM-1, ICAM-1, and CXCL1-coated wells was performed as previously described (17). Briefly, slides were coated with either 2% BSA (control; GE Healthcare) or PECAM-1 (2 μg/ml; R&D Systems), ICAM-1 (8 μg/ml; R&D Systems), and CXCL1 (10 μg/ml; PeproTech) overnight at 4°C. Isolated bone marrow neutrophils from WT, Mst1+/-, Rab27a–/–, Sytl1+/-, and Munc13–4o−/− mice were incubated on coated slides for 30 minutes at 37°C. Cells were fixed with 4% paraformaldehyde, blocked and permeabilized with PBS/0.1% Triton X-100/2% BSA, and stained with a mouse anti-VLA-3 antibody (42/CD49c; BD), rat anti-VLA-6 antibody (GoH3; BioLegend), rabbit anti-NE antibody (polyclonal; Abcam), sheep anti-Rab27a antibody (R&D Systems), and rabbit anti-MST1 antibody (polyclonal; Cell Signaling Technology). Primary antibodies were detected using goat anti-mouse–Alexa Fluor 488, goat anti-rabbit–Alexa Fluor 546, donkey anti-sheep–Alexa Fluor 488, and goat anti-rat-Alexa Fluor 647 ( Molecular Probes/Invitrogen), respectively. Cells were embedded in PermaFluor (Thermo Scientific) and imaged by confocal microscopy (Leica SP5 System, ×63, 1.4 NA oil objective). To investigate the translocation of VLA-3, VLA-6, NE, MST1, and Rab27a, fluorescence intensity profiles were obtained along a line through the cell as exemplified in Supplemental Figure 3A.

* In vivo NE activity assay. NE680FAST (4 nmol/mouse; PerkinElmer) was injected i.v. TNF-α (rmTNF-α; R&D Systems; 500 ng/mouse) was applied to the scrotum of WT and Mst1+/- mice 1 hour later. Two hours after TNF-α injection, the cremaster muscle was dissected and fixed with 4% paraformaldehyde, permeabilized and blocked.
with 0.5% Triton X-100/2% ovalbumin/PBS, stained with rat anti-PECAM-1 antibody–Alexa Fluor 488 (MEC13.3; BioLegend) or rabbit anti-MRP14 antibody (gift of Thomas Vogl, University of Münster, Münster, Germany), and detected with a goat anti-rabbit–Alexa Fluor 546 antibody (Invitrogen). Tissue was embedded on glass slides in PermaFluor (Thermo Scientific) and imaged by confocal microscopy (Leica SP5 system, ×40, 1.4 NA oil objective).

**Neutrophil fractionation.** Human blood neutrophils were isolated by Ficoll density centrifugation as previously described (59). For sucrose density gradient fractionation, supernatants of neutrophil lysates were placed on top of a continuous sucrose gradient (20%–70%) and spun down at 150,000 g for 1 hour at 4°C. Aliquots were collected from top to bottom and analyzed for the expression of MST1, Rab27a, and myeloperoxidase (24).

**Statistics.** All data were analyzed and plotted using GraphPad Prism 6 software (GraphPad Software Inc.). For pairwise comparison of experimental groups, a paired t test, unpaired t test, or Mann-Whitney test was performed. For comparison of 3 or more samples, a 1-way ANOVA was used with Dunnett’s multiple comparisons test. For multiple comparisons, a 2-way ANOVA was used with either Sidak’s multiple comparisons test or Tukey’s multiple comparisons test (comparison of all experimental groups against each other). A P value less than 0.05 was considered as statistically significant.

**Study approval.** Mst1−/− mice were generated by Dae-Sik Lim as described (60). Lyz2GFP mice (36) were generously provided by Thomas Graf (Centre for Genomic Regulation, Barcelona, Spain). Lyz2GFP × Mst1−/− mice were generated by crossbreeding. Rab27aash/ash mice were generated by crossbreeding. Munc13-4jinx/jinx knockout mice were housed by Serotec. Patient samples (94.0.89.2180.76505; E-mail: markus.sperandio@lmu.de). Human studies with purified neutrophils from parents (STK4+/−, STK4−/− patients, and adult healthy volunteers were approved by the ethics committee of Ludwig Maximilian University (AZ 66/14 and AZ 611/15).

**Author contributions**

ARMK, MP, and IR designed, performed, and analyzed experiments, interpreted data, and wrote the manuscript; MR, KS, UH, GG, and CN performed and analyzed experiments; BW, RI, JRW, and AM analyzed experiments; DSL and SD provided reagents critical for the project; MM, CK, DV, and RH contributed to the design of the experiments and the interpretation of the data; and MS and SDC designed experiments, interpreted data, and wrote the manuscript.

**Acknowledgments**

We thank Susanne Bierschenk, Nadine Schmidt, Eva Loell, and Jennifer Truong for excellent technical assistance.
